Case Study 1: An Evidence-Based Practice Review Report

Theme: School Based Interventions for Learning

How effective are Acceptance and Commitment Therapy based interventions delivered in school settings at reducing psychological distress in children and young people?

Summary

Acceptance and Commitment Therapy (ACT) is a form of psychotherapy. It uses mindfulness and acceptance techniques to try to help people cope with difficult feelings and take action according to their values (Hayes, Luoma, Bond, Masuda, & Lillis, 2006). It typically involves talk therapy and the use of metaphors, stories and mindfulness exercises. ACT has been used recently in secondary schools (e.g. Burckhardt, Manicavasagar, Batterham, & Hadzi-Pavlovic, 2016; Livheim et al., 2015) with the aim of reducing psychological distress (including depression, anxiety and stress) in young people.

This systematic literature review aims to investigate the evidence base for ACT-based interventions delivered in school settings. It will examine if they are effective at reducing psychological distress in children and young people. The main conclusion of the review is that there is not sufficient evidence for the effectiveness of these interventions. Reasons for this include poor methodological quality of studies and lack of replication of significant findings across studies.
Introduction

a. The need for therapeutic work in schools

There is increased concern over internalising disorders such as depression and anxiety in adolescents (Bor, Dean, & Najman, 2014). In the UK, the most recent Office of National Statistics Report found that one in ten children and young people had a diagnosable mental health disorder (Green et al., 2005). It is unknown whether there is now increased prevalence or better diagnosis and greater awareness. However, a recent report on child and adolescent mental health (Frith, 2016) found demand for services has increased in recent years and service users found the current level of access insufficient. Schools have been seen as appropriate locations for delivering psychological therapies since they may be more accessible than clinics, especially for children from disadvantaged families (Wolpert et al., 2011).

b. Acceptance and Commitment Therapy- Psychological Basis

Acceptance and Commitment Therapy (ACT) is a form of psychotherapy that attempts to change how a person views their thoughts and feelings. This is in contrast to challenging those thoughts directly as in Cognitive Behavioural Therapy (CBT) (Hayes, Strosahl, & Wilson, 1999). ACT is a transdiagnostic approach (Swain, Hancock, Dixon, & Bowman, 2015), meaning it was designed to alleviate a range of psychological conditions as well as chronic pain. ACT does not aim to eliminate psychological distress but helps people to choose to live how they want to despite difficult feelings. However, this is expected to lead to a reduction in psychological distress as people learn to accept their thoughts and feelings, seeing them as constructs rather than objective facts. ACT may currently be of interest due to the recent surge in popularity of mindfulness-based interventions in schools to enhance
mental health (Kallapiran, Koo, Kirubakaran, & Hancock, 2015). There are concerns that ACT and related therapies (e.g. Mindfulness Based Cognitive Therapy), classed as ‘third wave’, are not grounded in sufficient empirical evidence (Bass, van Nevel, & Swart, 2014). ‘Third wave’ therapies tend to focus on the function rather than the content of thoughts and behaviours as well as a person’s relationship to their thoughts and behaviours, which is referred to as ‘context’. (Hayes, 2004). Third wave therapies often include elements of mindfulness, acceptance and spirituality. The ‘first wave’ of behaviour therapies focused on behaviourist principles such as classical operant conditioning and the ‘second wave’ focused on cognition (Hayes, 2004). ACT researchers argue that ACT is not less effective than traditional CBT but that it currently lacks good quality research (Swain et al., 2015).

According to its founder, Steven Hayes, ACT is based on Skinner’s radical behaviourism whereby thoughts, feelings and language are regarded as internal ‘behaviours’ (Hayes et al., 2006). ACT targets the context and function of problematic thoughts rather than the thoughts themselves (Hayes, 2004) and is thus sometimes referred to as a contextual behaviour therapy. Psychological distress is thought to arise through normal, rather than pathological, human thought processes (Harris, 2006). Through interacting with their environments, people learn problem-solving processes that allow them to avoid or remove external threats. They then apply these processes to internal threats such as distressing thoughts and feelings. However, trying to control or avoid uncomfortable emotions and unhelpful thoughts can paradoxically exacerbate and strengthen them as the person unwittingly reinforces them, increasing their functional importance (Hayes et al., 2006). ACT provides an alternative way of approaching psychological distress through accepting
it and choosing to live life according to values rather than in order to avoid difficult thoughts and feelings.

The ACT literature does not tend to give precise definitions of psychological distress, preferring to regard ACT as a general approach to the problem of human suffering (Hayes, Strosahl & Wilson, 1999). Hayes, Strosahl & Wilson (1999) use terms such as ‘psychological distress’, ‘human suffering’, ‘psychopathology’, ‘psychological problems’ and ‘psychological suffering’ interchangeably. For the purpose of this review, the term ‘psychological distress’ was adopted. This can be defined as ‘mostly depression and anxiety symptoms that are indicative of a more or less intense feeling of emotional ill-being’ (Drapeau et al., 2010, p1).

Whilst depression and anxiety symptoms, rather than stress, are usually cited as the main features of psychological distress, there are theoretical and practical grounds for also including stress in the definition. Stress can be both positive (eustress) or negative (distress), as explored in the work of Selye (1974). However, scales used in psychological research tend to capture negative stress or ‘distress’ (Wheaton & Montazer, 2012), conceptualising it as a negative emotional state (Lovibond & Lovibond, 1995). Research has found that stress, as measured on some scales, may not be distinguishable from anxiety in young adolescents aged 11-14 years (Szabó & Lovibond, 2006). Stress also contributes to feelings of ‘emotional ill-being’ (Drapeau et al., 2010). High levels of negative stress are likely to cause suffering in the school age population and thus be of practical significance. Using the term ‘psychological distress’ in this review rather than a specific clinical term is more consistent with the theory behind ACT, which rather than a diagnostic approach, takes a dimensional view of mental health as emotional suffering (Waters, 2012). ACT employs six core
components to attempt to increase psychological flexibility and change the way the person interacts with their thoughts and feelings:

- Cognitive defusion (recognising thoughts as constructs, not objective facts)
- Acceptance
- Contact with the present moment (mindfulness)
- Observing the self
- Values
- Committed action

A typical ACT session includes experiential exercises where therapists or facilitators use stories, metaphors, mindfulness and language games to help people gain a different perspective on their thoughts and emotions (Harris, 2006). ACT was designed as an individual therapy but has been delivered as group psychotherapeutic or psychoeducational sessions in schools (Burckhardt, Manicavasagar, Batterham, & Hadzi-Pavlovic, 2016; Livheim et al., 2015). In one school, ACT was used as a basis for a life skills curriculum (Dixon, 2013). Adaptations for adolescents typically include using concrete props to illustrate metaphors, writing down thoughts in thought bubbles and using art and role-play (Halliburton & Cooper, 2014).

A recent review found emerging evidence that ACT can be effective in reducing symptoms of pain and psychological distress in children (Swain et al., 2015). However, most studies reviewed took place in clinical settings rather than schools. ACT has been found to be more effective than no treatment or placebo (Halliburton & Cooper, 2014) and one study found ACT outperformed traditional CBT in treating adolescent inpatients with depression (Hayes, Boyd, & Sewell, 2011).
c. Relevance to Educational Psychology Practice and Rationale for Review

Educational Psychologists (EPs) work with children and young people with a range of Special Educational Needs and Disabilities (SEND). This now explicitly includes ‘Social, Emotional and Mental Health’ needs, since the publication of the new SEND Code of Practice (Department for Education; Department of Health, 2014). A review of the roles and functions of EPs (Farrell et al., 2006) found service users wanted more therapy and intervention support. Mackay (2007) argues that EPs are particularly well-placed to deliver psychological therapies in schools due to their high level of training and position in the education system. There is ongoing discussion about how much EPs should engage in therapeutic work in schools (Wade, 2016). However, if they do this, they must make sure they are aware of what constitutes evidence-based practice (Dunsmuir & Hardy, 2016). This means having knowledge of different psychotherapeutic practices supported by high quality published studies.

ACT may be more developmentally appropriate for adolescents than younger children, requiring the use of abstract reasoning skills (Halliburton & Cooper, 2014). Mental health disorders often occur for the first time in adolescence (Murphey, Barry, & Vaughn, 2013), making access to services particularly important. There is very little evidence of the effectiveness of ACT with children under 11 (Swain et al., 2015).

Therefore, the question addressed in this review is:

How effective are Acceptance and Commitment Therapy based interventions delivered in school settings at reducing psychological distress in children and young people?
Critical Review of the Evidence

a. Literature Search and Screening Strategy

Searches were carried out in January 2017 in peer-reviewed journals using electronic databases PsychInfo, Medline and ERIC. These databases were chosen to give access to articles published in journals relating to health, psychology and education. The search included the following terms:

“acceptance and commitment therapy”
AND
child* or adolescen* or teenag* or school or young

The database search produced 390 text results. Titles and abstracts were screened according to inclusion criteria (Table 1) and 376 articles either did not meet criteria and were excluded or were found to be duplicates. Fourteen remaining articles were read in full and 10 were excluded with rationale (see Appendix A). An ancestral search was carried out on remaining articles and one further paper was identified. A graphical representation of this can be seen in Figure 1. One paper included two studies using different samples (Livheim et al., 2015). These two studies will be referred as Livheim et al., 2015a and Livheim et al., 2015b.

b. Weight of Evidence

The studies included in the review were evaluated according to Gough’s Weight of Evidence (WoE) framework (Gough, 2007). Each study was judged on methodological quality (WoE A), methodological relevance (WoE B) and topic relevance (WoE C). The scores for each of the three categories were summed and
divided by three to give an overall Weight of Evidence rating for the study (WoE D). Table 3 summarises the WoE scores given to each study in this review. In order to assess WoE A, two different protocols were used since the review includes studies using group designs and one with a small-N design. Protocols adapted from Kratochwill et al. (2003) and Horner et al. (2005) were used to evaluate WoE A for group designs and the small-N design respectively.

WoEs were assigned descriptions of ‘high’ if between 2.4 and 3.0, ‘medium’ if between 1.6 and 2.3 and ‘low’ if 1.5 or under.

**c. Participants**

In total, 612 participants took part in studies included in this review, aged from 11 to 21. A range of needs was present with considerable heterogeneity across studies. One study did not screen for need (Theodore-Oklota et al., 2014). One study (Burckhardt et al., 2016), conducted separate analyses of data of participants with
depressive or anxious symptoms. One study used referrals from school counsellors. One study (Livheim et al., 2015b) screened for participants. Two studies recruited students based on existing conditions, Autism Spectrum Disorder (ASD) (Pahnke et al., 2014) and Attention Deficit Hyperactivity Disorder (ADHD) (Murrell et al., 2015). This is likely to have impacted on outcomes. Presenting problems of the sample were assessed in WoE C with lower ratings given to studies whose analyses were not clearly of participants starting the study with psychological distress.

Studies took place in a variety of settings in the USA, Sweden and Australia. These are OECD countries with education systems broadly similar to the UK. Therefore, country was not thought to impact highly on WoE for this research question. Two took place in special schools (Murrell et al., 2015; Pahnke et al., 2014), limiting their generalisability to other special schools. Four studies took place in mainstream schools, limiting their generalisability to other mainstream schools. Two of these mainstream schools were particularly affluent environments (Burckhardt et al., 2016; Livheim et al., 2015b). Again, this limits their generalisability to a particularly priviledged student population. One study (Livheim et al., 2015a) included five different schools, one of which was an alternative school for students unable to cope with mainstream educational settings and therefore may have higher external validity since the participants were drawn from multiple settings. Setting was taken into account for WoE C.

Both sexes were represented in the overall sample. Four studies included considerably higher numbers of either boys (Pahnke et al., 2014; Burckhardt et al.,
2016) or girls (Livheim et al., 2015, both studies). This limits the generalisability of these studies to the sex that was studied and was taken into account in WoE C.

Three group studies were underpowered to detect even a large effect (Livheim et al., 2015a and b; Pahnke et al., 2014). Burckhardt et al., (2016) had only enough power to detect a large effect and Theodore-Oklotá et al., (2014) had enough power to detect either medium or large effects. Cohen (1992) suggests 26 per group for a large effect, 64 per group for a medium effect and 393 for a small effect when significance level is .05 and power is .08. This could partly explain why findings were inconsistent (Maxwell, 2004). This was reflected when judging WoE A and led to five out of the six studies in this review receiving a ‘low’ rating in this category.

d. Randomisation

Only one study was fully randomised (Livheim et al., 2015b) and obtained the highest rating on WoE B since randomisation makes groups more likely to be equivalent, allowing researchers to draw more valid conclusions about the true effect of the intervention on the outcome (Barker, Pistrang, & Elliott, 2016). Three studies randomised whole classes to conditions (Burckhardt et al., 2016; Theodore-Oklotá et al., 2014; Pahnke et al., 2014). One study randomised female participants but allocated all male participants to the intervention (Livheim et al., 2015a). Murrell et al. (2015) employed a small N design, therefore receiving a low score on WoE B due to substantial threats to internal consistency for which authors did not compensate.
e. Intervention Content and Fidelity

All interventions were based on ACT but their content varied, as did their fidelity. Livheim et al. (2015a and b) used the same manualized ‘ACT Experiential Adolescent Group’ programme, available online from the Association of Contextual Behavioural Science (https://contextualscience.org/). This programme involves all six components of ACT as well as art and role-play. The Australian study (Livheim et al., 2015a) reported using this manualized version. The Swedish study (Livheim et al., 2015b) translated the programme into Swedish and adapted it to treat stress and to fit into a six week period. Description of adaptations were insufficient for replication and this was reflected in lower WoE A ratings.

Four studies describe ACT-based interventions created by their authors. Pahnke et al., (2014) modified an existing adult ACT protocol although again did not describe adaptations sufficient for replication. Burckhardt et al., (2016) created a new programme, ‘Strong Minds’, drawing on Positive Psychology and all 6 ACT components. This makes it hard to determine whether ACT components led to participant change. Murrell et al. (2015) based their intervention on a pre-existing protocol, ‘ACT for kids’, developed by the lead author and a co-author. They describe how they ‘carefully noted’ adherence to and deviation from ‘ACT for kids’ but this information is not available in the paper. Theodore-Okloita et al., (2014) did not report using or basing their intervention on a published protocol. Additionally the description of the intervention in the paper does not explicitly include all six ACT components; therefore, this study could only be given a ‘low’ rating for this aspect of WoE C.
Interventions were delivered by psychology students (Pahnke et al., 2014; Livheim et al., 2015b; Theodore-Oklota et al., 2014), psychologists (Burckhardt et al., 2016; Livheim et al., 2015a) or a ‘recognised ACT trainer’ (Murrell et al., 2015). One study (Burckhardt et al., 2016) was audiotaped and coded for treatment fidelity on an adherence scale by a psychologist experienced in ACT and therefore scored more highly for WoE A. Where there were comparison groups, these were run by school staff whereas intervention groups were run by psychologists or psychology students. No study counterbalanced change agents so experimenter effects may have influenced outcomes. Facilitator supervision was mentioned explicitly in three studies (Burckhardt et al. 2016; Livheim et al., 2015a; Theodore-Oklota et al., 2014). Supervision was thought to enhance fidelity therefore studies mentioning it explicitly scored higher on WoE A.

**f. Comparison Condition**

To receive a ‘high’ rating for comparison condition, studies needed to use an active comparison group also receiving psychotherapeutic support e.g. CBT. No study in this review did this, therefore it compromises findings since many forms of psychotherapy are broadly equivalent in effect (Barker, Pistrang & Elliott, 2016) and it cannot be concluded that the ACT components led to change. One study used a comparison group receiving pastoral care classes of the same length and duration as the ACT group (Burckhardt et al., 2016) and received a ‘medium’ rating for this criterion. Two involved monitoring or an offer of individual support but not all participants took this up (Livheim et al., 2015 a and b). Two used a waitlist control and one did not use a comparison condition. These obtained a lower score for WoE
B since their design meant that expectancy effects or the Hawthorne effect, rather than the ACT components of the intervention, may have led to change.

g. Measures
Most studies reviewed did not collect data from multiple sources or using multiple methods. When multiple sources were attempted, the measure used was either inappropriate (Pahnke et al., 2014) or staff and parents did not complete questionnaires (Murrell et al., 2015). Therefore, they could not score highly on WoE. One study collected data on stress using two different scales (Livheim et al., 2015b) and found that participants improved according to one scale but not according to the other.

One study (Pahnke et al., 2014) used inappropriate measures. Authors used the Stress Schedule Survey as a self-report measure although it only has validity and reliability as a parent or teacher-report measure. They also used the Beck Youth Inventories for participants up to age 21 even though they only have validity and reliability for under 18s. This study received a rating of ‘0’ for measurement and its findings must be viewed particularly critically.

h. Outcomes
There is an inconclusive picture of the effectiveness of ACT-based interventions from studies in the present review. Effect sizes for group studies were calculated by subtracting the mean pre-post change in the intervention group from the mean pre-post change in the comparison group and dividing this by the pooled pre-test standard deviation, as recommended by Morris (2008). Effect size for small-N
studies is typically calculated using Percentage of Non-overlapping Data Points (PAND). This was not possible since Murrell et al. (2015) only gave two data points for each participant. Therefore, effect size for this study was calculated by looking at within-participant pre-post change (Becker, 1988). Effect sizes were reported for depression (Table 4), anxiety (Table 5) and stress (Table 6) separately. Effect sizes for psychological distress (Table 7) were reported for studies that used a general measure or also included a composite score. Positive effect sizes mean psychological distress reduced more in the intervention group than the comparison group whereas a negative number means psychological distress reduced more in the comparison group. Effect sizes were calculated even for non-significant findings to investigate whether Type 2 errors were made due to studies being underpowered. Effects were interpreted according to Cohen's criteria (1992) of 0.2 as small, 0.5 as medium and over 0.8 as large. Effects below 0.2 were regarded as negligible.

One study found a medium effect of ACT-based interventions on reducing depression (Burckhardt et al., 2016) and another found a large effect (Livheim et al., 2015a). Two studies found nil effects for this outcome (Livheim et al., 2015b; Pahnke et al., 2014).

Three studies measured anxiety pre and post intervention and all found nil effect on their group of participants as a whole (Burckhardt et al., 2016; Livheim et al., 2015b, Pahnke et al., 2014). However, the Livheim et al. (2015b) study was underpowered and may have produced a Type 2 error due to too few participants (see Table 5). When Burckhardt et al. (2016) reran their analysis, separating participants by year group, they found a medium effect on anxiety in the Year 10 participants only.
Two studies found large effects of ACT-based intervention on stress (Burckhardt et al., 2016; Livheim et al., 2015b) and one study found a medium effect (Pahnke et al., 2014). However, Livheim et al. (2015b) and Pahnke et al. (2014) both used two measures to investigate stress and both found nil effects on the alternative measure. This calls their findings into question.

One study found a medium effect of ACT-based intervention on psychological distress taken as a whole (Burckhardt et al., 2016). Two (Theodore-Oklota et al., 2014; Pahnke et al. 2014) found nil effect of ACT-based intervention on overall psychological distress at post-intervention test. Murrell et al. (2015) found reliable change for five out of seven participants but three of these changed in the undesired direction. Effect size was large, suggesting that psychological distress increased in this group. However, methodology was poor and there were too few participants to trust the results of this analysis.

i. Educational/Clinical Significance
One study (Burckhardt et al., 2016) classified levels of psychological distress according to clinical categories. They found clinical differences on anxiety (for Year 10 only) and stress (for both year groups). Therefore, this study obtained a higher score for WoE A.

j. Follow Up
One study (Pahnke et al., 2014) did a follow up, re-administering measures two months after intervention completion. To avoid multiple comparison issues and Type
error, they did not calculate differences between post and follow-up scores separately, presenting figures with results of ANOVAs examining data at times 1, 2 and 3 in a single analysis. Trends show effects of the intervention on stress (Stress Schedule Survey) and psychological distress overall (Beck Youth Inventories total score) becoming significant only at follow-up. Since effects were not calculated, follow-up was not included in WoE ratings.

Conclusions and Recommendations

In conclusion, evidence for the effectiveness of ACT-based interventions delivered in school settings at reducing psychological distress (depression, anxiety and stress) in children and young people is limited. This lack of convincing evidence is due to poor methodological quality of the studies reviewed and lack of significant outcomes found in several studies. Five out of six studies reviewed received a rating of ‘low’ for methodological quality, making it difficult to draw any firm conclusions from their findings.

Studies were heterogeneous in content, setting and sample. Therefore, it is hard to draw conclusions on why some found large effect sizes for some outcomes and others found no effects. It could be a consequence of all but one of the studies being underpowered (Maxwell, 2004). However, the studies that did find significant effects were of better methodological quality (Burckhardt et al., 2016; Livheim et al., 2015a and b) and had some common elements. They included 6 to 16 sessions whereas two studies with worse outcomes (Pahnke et al., 2014; Theodore-Okloeta et al., 2014) included only two to three sessions. They were delivered by psychologists rather than by students. They took place in mainstream schools and in two cases the sample had a high socioeconomic status background (Burckhardt et al., 2016; Livheim et al., 2015b). They used measures intended to capture changes in mental health rather than behaviour. This indicates that future research should investigate ACT-based interventions delivered by a psychologist of at least 6 sessions in length, using measures designed to capture changes in mental health. Better quality research is needed, particularly in settings with students attending special schools and from more diverse socioeconomic backgrounds.
The study of the highest methodological quality (Burckhardt et al., 2016) is the only one in this review to provide good evidence of reduction in psychological distress after ACT-based intervention. However, no firm conclusions can be drawn about whether this was due to the ACT components of the intervention. This is because most major forms of therapy are broadly equivalent in effect (Barker et al., 2016). Alternatively, the students who improved may have done so due to expectancy effects or the Hawthorne effect. To understand whether ACT-specific components of the intervention led to change, future research should use a comparison group also receiving psychotherapeutic input e.g. CBT. Despite this, EPs may find this study interesting as a general indication of the potential effectiveness of psychotherapeutic input in schools.

When evaluating psychotherapy, practitioners should be aware that EPs work with adolescents with a range of complex needs. Participants in RCTs and similar designed studies often systematically differ from adolescents seen routinely for psychotherapy, having less severe and fewer comorbid issues (Wolpert, Fugard, & Deighton, 2013). As well as basing practice on evidence, EPs must take into account the local context and presenting problems of the child or young person. ACT may be more appropriate for adolescents experiencing unavoidable psychological distress, for example arising from chronic pain or life-limiting conditions, due to its focus on acceptance. EPs interested in ACT would be advised to proceed with caution due to the current lack of evidence and to carefully evaluate outcomes using Goal Attainment Scaling or Target Monitoring and Evaluation (Dunsmuir, Brown, Iyadurai, & Monsen, 2009). If done rigorously and replicated sufficiently as detailed by
Wolpert, Fugard and Deighton (2013), evaluation could build up a body of practice-based evidence to complement any future RCTs in the field.

Due to the limitations discussed in this review, EPs should be clear that there is currently insufficient evidence to recommend the use of ACT based interventions in schools. Future studies, including evaluation of outcomes by practitioners, should strive for better methodological quality. Future RCTs should ensure they have sufficient power to detect effects and include an active psychotherapy control to identify the effective components of interventions.

Weight of Evidence Ratings

Weight of Evidence A

Group Studies

Weight of Evidence A was determined by using adapted non-review specific protocols based on the work of Kratochwill et al., (2003) for group studies and Horner et al. (2005) for the small N case design.

The Kratochwill et al., (2003) protocol was adapted to suit this review by removing sections on identifiable components, replication, site of implementation and follow-up assessment.

Table 9

<table>
<thead>
<tr>
<th>Section removed from protocol</th>
<th>Rationale for removal</th>

Small N study

The Horner et al. (2005) protocol was used in full. This was used for the Murrell et al. (2015) study as it employed a small-N case design. The quality indicators detailed in Table 1 of the Horner et al. (2005, p175) paper were used as criteria for Weight of Evidence A. The descriptors used by Horner and colleagues were used to give different possible numerical ratings. To arrive at a total Weight of Evidence A for the small N study, ratings for all criteria were summed and divided by 7, which was the total number of criteria.
Table 12  
*Weight of Evidence A Criteria for small-N study*

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Ratings</th>
</tr>
</thead>
</table>
| A: Description of Participants and Setting | 3. All 3 of the following criteria are fulfilled: participants are described with sufficient detail to allow others to select individuals with similar characteristics (e.g., age, gender, disability, diagnosis); the process for selecting participants is described with replicable precision; critical features of the physical setting are described with sufficient precision to allow replication.  
2. Two out of the criteria above are fulfilled.  
1. One of the criteria above is fulfilled. |
| B: Dependent Variable | 3. All of the following criteria are fulfilled: dependent variables are described with operational precision; each dependent variable is measured with a procedure that generates a quantifiable index; measurement of the dependent variable is valid and described with replicable precision; dependent variables are measured repeatedly over time; data are collected on the reliability or interobserver agreement associated with each dependent variable, and IOA levels meet minimal standards (e.g., IOA = 80%; Kappa = 60%).  
2. Three to four of the above criteria are fulfilled.  
1. One to two of the above criteria are fulfilled. |
| C: Independent Variable | 3. All of the following criteria are fulfilled: independent variable is described with replicable precision; independent variable is systematically manipulated and under the control of the experimenter; overt measurement of the fidelity of implementation for the independent variable is highly desirable.  
2. Two of the above criteria are fulfilled.  
1. One of the above criteria is fulfilled. |
D: Baseline

3. All of the following criteria are fulfilled: the study includes a baseline phase that provides repeated measurement of a dependent variable; the study establishes a pattern of responding that can be used to predict the pattern of future performance, if introduction or manipulation of the independent variable did not occur; baseline conditions are described with replicable precision.

2. Two of the above criteria are fulfilled.

1. One of the above criteria is fulfilled.

E: Experimental Control/Internal Validity

3. All of the following criteria are fulfilled: the design provides at least three demonstrations of experimental effect at three different points in time; the design controls for common threats to internal validity (e.g., permits elimination of rival hypotheses); the results document a pattern that demonstrates experimental control.

2. Two of the above criteria are fulfilled.

1. One of the above criteria is fulfilled.

F: External Validity

3. Experimental effects are replicated across 3 or more participants and also either settings or materials to establish external validity.

2. Experimental effects are replicated across 3 or more participants

1. Experimental effects are replicated by inclusion of at least 2 participants.

G: Social validity

3. All of the following criteria are fulfilled: the dependent variable is socially important; the magnitude of change in the dependent variable resulting from the intervention is socially important; implementation of the independent variable is practical and cost effective; social validity is enhanced by implementation of the independent variable over extended time periods, by typical intervention agents, in typical physical and social contexts.

2. Two to three of the above criteria are fulfilled.

1. One of the above criteria is fulfilled.

Weight of Evidence B

Weight of Evidence B was determined by review-specific criteria relating to methodological relevance. Different criteria were used for group studies and single case designs. To receive weightings of two or three, the study must have employed a group design.

Table 14
Weight of Evidence B Criteria

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Ratings</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>A: Randomisation procedure</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1. Group study with no randomisation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2. Group study with cluster randomisation (e.g. by classroom) or partial individual randomisation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Group study with full individual randomisation of participants to intervention or control group</td>
<td></td>
<td>Full individual randomisation allows conclusions about causality to be drawn more convincingly. Pre-existing groups may differ systematically.</td>
</tr>
<tr>
<td>B: Comparison group</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Comparison group also receives psychotherapeutic support in the same format as intervention group e.g. CBT, other talk therapy</td>
<td></td>
<td>If other psychotherapeutic support is offered to control group in same format, more secure conclusions can be drawn that it is the ACT component of the intervention that is bringing about change. If not, positive effects of programme may be due to social support in</td>
</tr>
</tbody>
</table>
2. Comparison group receives an intervention in same format as intervention group but this may not be psychotherapy.

1. Comparison group receives little or no alternative intervention.

Ratings for criteria A and B were summed and divided by two to arrive at a score for Weight of Evidence B.

<table>
<thead>
<tr>
<th>Authors</th>
<th>Dimensions</th>
<th>Total WoE B</th>

<td>2 1</td>
<td>1.5</td>
</tr>
</tbody>
</table>

The Murrell et al., (2015) study was a small N design and was assigned an overall WoE B of one since it did not employ randomisation or a comparison group.

**Weight of Evidence C**

Weight of Evidence C was determined by review-specific criteria relating to topic relevance.

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Ratings</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>A: ACT components</td>
<td>3. All components of ACT are evident in the intervention</td>
<td>Review attempts to test the effectiveness of ACT-based</td>
</tr>
</tbody>
</table>
(cognitive defusion, acceptance, contact with the present moment, observing the self, values and committed action).

2. At least 4 components of ACT are evident in the intervention

1. 1-3 components of ACT are evident in the intervention or information on intervention components is not stated

<table>

<tbody>
<tr>
<td>B: Presenting problems of sample</td>
<td>3. Sample is screened and found to be experiencing mild-moderate psychological distress (depression, anxiety or stress) according to diagnostic criteria or a valid and reliable scale</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Sample is nominated by staff as experiencing or likely to be experiencing mild-moderate psychological distress (depression, anxiety or stress) but this has not been validated by a diagnostic process, psychological assessment or screening tool.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>OR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Sample has a diagnosed psychological condition e.g. ASD and authors make a case for children and young people with this condition commonly experiencing psychological distress</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. Sample has no identified psychological condition or authors do not link the psychological condition they have to psychological distress</td>
<td></td>
</tr>
<tr>
<td>C: Intention of Intervention</td>
<td>3. Intervention was planned to reduce psychological distress (stress, anxiety, depression)</td>
<td></td>
</tr>
</tbody>
</table>
2. Intervention was planned to help a different psychological condition

1. No clear rationale for intervention

<table>

</tbody>
</table>

Ratings for criteria A, B and C were summed and divided by three to arrive at a score for Weight of Evidence C.

Weights of Evidence A, B and C were summed and divided by 3 to arrive at a total score for Weight of Evidence D.
Appendix D

Example of Coding Protocol for Group Designs (Kratochwill et al., 2003)

1. Burckhardt et al. (2016)

Date 05.02.2017

Full Study Reference in proper format:

(Burckhardt et al., 2016)

☐ Type of Publication:
☐ Book/Monograph
☒ Journal Article
☐ Book Chapter
☐ Other (specify):

1. General Characteristics

A. General Design Characteristics

A1. Random assignment designs (if random assignment design, select one of the following)

☐ Completely randomised design
☐ Randomised block design (between participants, e.g., matched classrooms)
☐ Randomised block design (within participants)
☐ Randomised hierarchical design (nested treatments)
☒ Cluster randomisation (8 tutorial groups randomised to intervention group, 8 to control group)

A2. Nonrandomised designs (if non-random assignment design, select one of the following)

☐ Nonrandomised design
☐ Nonrandomised block design (between participants)
☐ Nonrandomised block design (within participants)
☐ Nonrandomised hierarchical design
☐ Optional coding for quasi-experimental designs

A3. Overall confidence of judgment on how participants were assigned (select one of the following)

☐ Very low (little basis)
☐ Low (guess)
☐ Moderate (weak inference)
☐ High (strong inference)
☒ Very high (explicitly stated)
☐ N/A
☐ Unknown/unable to code

B. Participants

Total size of sample (start of study): __63__
Intervention group sample size: ___30___

Control group sample size: ___33___

C. Type of Program

☐ Universal prevention program
☐ Selective prevention program
☐ Targeted prevention program
☐ Intervention/Treatment
☐ Unknown

D. Stage of Program

☐ Model/demonstration programs
☐ Early stage programs
☐ Established/institutionalized programs
☐ Unknown

E. Concurrent or Historical Intervention Exposure

☐ Current exposure
☐ Prior exposure
☒ Unknown

2. Key Features for Coding Studies and Rating Level of Evidence/Support

(Rating Scale: 3= Strong Evidence, 2=Promising Evidence, 1=Weak Evidence, 0=No Evidence)

A. Measurement (Estimating the quality of the measures used to establish effects)

A1 The use of the outcome measures produce reliable scores for the majority of the primary outcomes

☒ Yes
☐ No
☐ Unknown/unable to code

A2 Multi-method (at least two assessment methods used)

☐ Yes
☒ No (different scales were used but to assess different constructs e.g. depression, anxiety, stress, "flourishing")
☐ N/A
☐ Unknown/unable to code

A3 Multi-source (at least two sources used self-reports, teachers etc.)

☐ Yes
☒ No
☐ N/A
☐ Unknown/unable to code

A4 Validity of measures reported (well-known or standardized or norm-referenced are considered good, consider any cultural considerations)

☐ Yes validated with specific target group
☒ In part, validated for general population only
☐ No
Overall Rating for measurement_________________________1____________________

3= Strong Evidence  2=Promising Evidence 1=Weak Evidence  0=No Evidence

B. Comparison Group

B1 Type of Comparison Group (Select one of the following)
- [ ] Typical intervention (typical intervention for that setting, without additions that make up the intervention being evaluated) Usual pastoral care classes
- [ ] Attention placebo
- [ ] Intervention element placebo
- [ ] Alternative intervention
- [ ] Pharmacotherapy
- [ ] No intervention
- [ ] Wait list/delayed intervention
- [ ] Minimal contact
- [X] Unable to identify type of comparison

B2 Overall confidence of judgment on type of comparison group
- [ ] Very low (little basis)
- [ ] Low (guess)
- [ ] Moderate (weak inference)
- [ ] High (strong inference)
- [X] Very high (explicitly stated)
- [ ] Unable to identify comparison group

B3 Counterbalancing of change agent (participants who receive intervention from a single therapist/teacher etc. were counter-balanced across intervention)
- [ ] By change agent
- [ ] Statistical (analyse includes a test for intervention)
- [ ] Other
- [X] Not reported/None School staff ran pastoral care classes

B4 Group equivalence established (select one of the following)
- [ ] Random assignment
- [ ] Posthoc matched set
- [ ] Statistical matching
- [X] Post hoc test for group equivalence- no significant differences on baseline scores or demographics found

B5 Equivalent mortality
- [X] Low attrition (less than 20 % for post) (9% in control condition and 8.2% in intervention condition)
- [ ] Low attrition (less than 30% for follow-up)
- [ ] Intent to intervene analysis carried out?
  Findings_____________

Overall rating for Comparison group _______2___________

3= Strong Evidence  2=Promising Evidence 1=Weak Evidence  0=No Evidence

C. Appropriate Statistical Analysis

Analysis 1__________DASS___________________________
Appropriate unit of analysis
☑ Familywise/experimenter wise error rate controlled when applicable
☑ Sufficiently large N- (large sample used but only 63 for DASS because they only looked at the students who began programme with elevated symptoms)

Overall rating for statistical analysis _________1_________
3= Strong Evidence 2=Promising Evidence 1=Weak Evidence 0=No Evidence

D. Educational/Clinical Significance

Study must provide evidence in support of the clinical significance for:

☑ Categorical Diagnosis Data
☑ Outcomes Assessed Via Continuous Variables
☑ Subjective Evaluation
☑ Social Comparison

Overall rating for educational/clinical significance _________1_________
3= Strong Evidence 2=Promising Evidence 1=Weak Evidence 0=No Evidence

E. Fidelity

Evidence of adherence is measured through
☑ Ongoing supervision/consultation
☑ Coding sessions
☑ Audio/video tapes
☑ Use of a manual
☑ There is a description of any adaptations.

Overall rating for fidelity _________3_________
3= Strong Evidence 2=Promising Evidence 1=Weak Evidence 0=No Evidence

Coding protocol for Single Case Research (Horner et al., 2005.)

See Table 12 for explanation of criteria used to rate this study.

Murrell et al. (2015)

**Section A: Description of Participants and Setting**

1) Participants are described with sufficient detail to allow others to select individuals with similar characteristics; (e.g., age, gender, disability, diagnosis).

*Yes*

*No* – they all have ADHD but also ‘comorbid LDs and/or disruptive behaviour’- not specified exactly what. Gender and age are given.

*N/A*

Unknown/Unable to Code

2) The process for selecting participants is described with operational precision.

*Yes*

*No* – they ‘volunteered’

*N/A*

Unknown/Unable to Code

3) Critical features of the physical setting are described with sufficient precision to allow replication.

*Yes*

*No*

*N/A*

Unknown/Unable to Code

Overall Rating of Evidence: 1

**Section B: Dependent Variable**

1) Dependent variables are described with operational precision.

*Yes* - Behavior Assessment System for Children, 2 (BASC-2).

*No*

*N/A*

Unknown/Unable to Code

2) Each dependent variable is measured with a procedure that generates a quantifiable index.

*Yes*

*No*

Unknown/Unable to Code
3) Measurement of the dependent variable is valid and described with replicable precision.
   Yes
   No
   N/A
   Unknown/Unable to Code

4) Dependent variables are measured repeatedly over time.
   Yes
   No
   N/A
   Unknown/Unable to Code

5) Data are collected on the reliability or inter-observer agreement associated with each dependent variable, and IOA levels meet minimal standards (e.g., IOA = 80%; Kappa = 60%).
   Yes – see BASC 2 article
   No
   N/A
   Unknown/Unable to Code

Overall Rating of Evidence: 2

Section C: Independent Variable

1) Independent variable is described with replicable precision.
   Yes
   No- details of intervention are given but not enough to replicate the study precisely
   N/A
   Unknown/Unable to Code

2) Independent variable is systematically manipulated and under the control of the experimenter.
   Yes
   No
   N/A
   Unknown/Unable to Code

3) Overt measurement of the fidelity of implementation for the independent variable is highly desirable.
   Yes
   No
   N/A
   Unknown/Unable to Code

Overall Rating of Evidence: 0
Section D: Baseline

1) The majority of single-subject research studies will include a baseline phase that provides repeated measurement of a dependent variable and establishes a pattern of responding that can be used to predict the pattern of future performance, if introduction or manipulation of the independent variable did not occur.

Yes
No
N/A
Unknown/Unable to Code

2) Baseline conditions are described with replicable precision.

Yes
No
N/A
Unknown/Unable to Code

Overall Rating of Evidence: 0

Section E: Experimental Control/Internal Validity

1) The design provides at least three demonstrations of experimental effect at three different points in time.

Yes
No
N/A
Unknown/Unable to Code

2) The design controls for common threats to internal validity (e.g., permits elimination of rival hypotheses).

Yes
No
N/A
Unknown/Unable to Code

3) The results document a pattern that demonstrates experimental control.

Yes
No – no effect was found
N/A
Unknown/Unable to Code

Overall Rating of Evidence: 0

Section F: External Validity

1) Experimental effects are replicated across participants, settings, or materials to establish external validity.

Yes - multiple participants were used but no effect found
Overall Rating of Evidence: 2

Section G: Social Validity

1) The dependent variable is socially important.
   Yes- emotional distress
   No
   N/A
   Unknown/Unable to Code

2) The magnitude of change in the dependent variable resulting from the intervention is socially important.
   Yes
   No- no change effect found
   N/A
   Unknown/Unable to Code

3) Implementation of the independent variable is practical and cost effective
   Yes
   No- delivered by researcher trained in ACT
   N/A
   Unknown/Unable to Code

4) Social validity is enhanced by implementation of the independent variable over extended time periods, by typical intervention agents, in typical physical and social contexts.
   Yes
   No- researcher trained in ACT needed, lots of rewards necessary to get students to go to group, teachers did not fill in Qaires
   N/A
   Unknown/Unable to Code

Overall Rating of Evidence: 1

A: 1
B: 2
C: 0
D: 0
E: 0
F: 2
G: 1

Average WoE A = 0.9
Sum of X / N
X = individual quality rating for each judgement area
N = number of judgement areas
