Case study 1: An Evidence-based practice review report.

Theme: School/Setting Based Interventions for Social, Emotional and Mental Health.

How effective are school-based Attribution Retraining interventions in reducing peer-directed aggression in school children?

Summary

The purpose of this review is to evaluate the effectiveness of school-based Attribution Retraining (AR) interventions in reducing peer-directed aggression in school-aged children. Attributions are inferences that people make about others’ feelings and beliefs, in order to understand the intent behind their behaviour. Dodge and Coie (1987) argue that maladaptive attributions can lead to situations of causal uncertainty being perceived as hostile, which can lead to aggressive behaviour. AR has been suggested as a means of identifying these attributions and making them more adaptive, to reduce aggressive behaviour (Vassilopoulos et al., 2015). This review sought to evaluate the efficacy of AR interventions in reducing hostile attributions and, in turn, aggressive behaviour within a school context. A comprehensive literature search returned five studies, which met the review’s inclusion criteria. These were evaluated using Gough’s (2007) Weight of Evidence (WoE) Framework. A meta-analysis was carried out and showed a large combined effect size when comparing AR interventions to the ‘no-intervention’ control group in each study. This, along with the medium to large overall quality of the reviewed studies, suggests school-based AR interventions can be recommended as evidence-based practice (Gersten et al., 2005) in reducing aggression in school-age populations. Limitations of the review, along with
recommendations for educational psychology practice and for future research, are discussed.

Introduction

Attribution Theory

Attribution Theory (AT) proposes that individuals seek to determine the cause of observable behaviours and outcomes (Heider, 1958), and attribute feelings, beliefs, and intentions to others in an attempt to explain what they have observed. An individual may believe the cause to be: internal or external; controllable or uncontrollable; stable or unstable (Weiner, 1985). Their interpretation will impact their thoughts and, in turn, their subsequent behaviour (Frederickson & Cline, 2007).

In relation to aggression, AT has been used to aid understanding of how an individuals’ perception of an event can lead to aggressive behaviour. Crick and Dodge (1994) believe that a child’s behaviour results from six sequential steps of processing: (1) encoding of social cues; (2) interpreting social cues; (3) selection of goals; (4) generation of response; (5) response evaluation; and (6) enacting of behaviour, with item (2) being considered fundamental. This is because, if social cues are misinterpreted as ambiguous peer provocations, it can affect the child’s wellbeing (Dodge, 2006) and potentially lead to aggressive behaviour.

Research demonstrates that some aggressive individuals may have a hostile attribution bias (Nasby et al., 1980), which leads to situations of causal ambiguity being perceived as provocative (Van Bockstaele et al., 2020). The causes of this have been attributed to executive functioning deficits (Verhoef et al., 2019); cognitive
processing difficulties (Dodge et al., 1986); traumatic life events (Frederickson & Cline, 2007); early adverse childhood experiences (Verhoef et al., 2019); harsh parenting and peer rejection (Dodge, 1980). Dodge’s (2006) model of social information processing provides support for this theory. The model states that aggressive individuals are more likely to interpret others’ motives as confrontational in ambiguous situations, rather than harmless or neutral.

Social Cognitive Theory states that this can lead to the development and maintenance of aggression (Verhoef et al., 2019), with individuals becoming aggressive as a way to retaliate or defend themselves. This maintenance occurs due to the aggressive individual not having the opportunity to challenge their hostile beliefs or learn more prosocial behaviour strategies. A vicious cycle can then be generated where hostile attribution bias leads to aggression and further rejection by their peer group. This can then lead the aggressive individual to perceive the world as a hostile place and this perpetuates their aggressive behaviour.

The role of hostile attribution bias in developing and perpetuating aggressive behaviour has been supported in longitudinal (Lansford et al., 2010), experimental (Lochman & Dodge, 1998), and longitudinal-experimental studies (Lochman & Wells, 2002). This provides a rationale for an intervention that educational psychologists (EPs) can recommend, which focuses on adapting attribution bias in order to reduce aggressive behaviour.

**Attribution Retraining (AR)**

AR aims to identify maladaptive causal attributions, challenge misconceptions and help individuals learn more adaptive ways of perceiving and interpreting themselves
and others. In this review, this means adapting a child’s hostile attribution bias in order to reduce their aggressive behaviour.

AR interventions have been studied in a variety of settings, including clinics (Hilt, 2004) and schools (Robertson, 2000), and have been shown to be successful in adapting attributions relating to achievement (Chodkiewicz & Boyle, 2014), as well as behaviour (Lapointe & Legault, 2004). There are dedicated AR programs, such as the Brain Power Program (Hudley et al., 1994), as well as study-specific AR interventions (Vassilopoulos et al., 2015; Van Bockstaele et al., 2020). This means that studies on AR interventions can vary according to: environmental factors; length of the intervention; number of sessions; content and target group. They have also been carried out on whole classes (Ziegler & Heller, 2000) and smaller groups (Chodkiewicz & Boyle, 2014). Content delivery can also vary depending on the methods used, such as the use of written resources (Vassilopoulos et al., 2015) and video simulations (Van Bockstaele et al., 2020) and techniques employed can also vary and include: persuasion; motivation; problem-solving; modelling; calming exercises and the use of self-talk.

**Rationale and Relevance**

One of the most common forms of social difficulty among school-aged children is the exhibiting of externalising behaviours such as aggression and anger (Wilmshurst, 2009). These result in difficulties with peer relationships, poor self-concept and academic underachievement in the short term (Vassilopoulos et al., 2015) and can lead to substance misuse and criminality in the long term (Reef et al., 2011). This highlights the need for effective strategies to be put in place in order to support children in reducing these behaviours.
It is important that any intervention adopted to support children with these difficulties are evidence-based and relevant contextually. An EP can play an important role in supporting children with these difficulties through identifying areas of need, within the school and the child, and recommending appropriate interventions that match the individual context. An EP can also oversee implementation and support monitoring and evaluation.

It is important that EPs play a role in supporting these children as otherwise they can be at risk of both social and school exclusion (Reed, 1988), especially if staff do not understand that the child’s behaviour could be a means of communicating that they feel threatened.

Research linking the use of AR with aggressive children dates back to the 1970s with Harris and Huang (1974) reporting that the cognitive attribution theory of emotion was important in explaining aggressive behaviour. This was supported by Graham (1997) who found that students who had been labelled ‘aggressive’ were biased towards perceiving peer provocation as intentional. Through the use of AR, Graham showed that those who received AR had altered attributions and emotional reactions post-training, which indicates that AR may be an approach EPs could recommend to schools. However, despite the reported success of AR in reducing aggressive behaviour, the majority of the research has been conducted outside of the UK. Therefore, there is a need to assess the true effectiveness of AR interventions before ascertaining if they should be recommended for implementation by EPs within a UK context.

**Review Question**
How effective are school-based Attribution Retraining interventions in reducing peer-directed aggression in school children?

Critical Review of the Evidence Base

Literature search

A systematic literature search using the Web of Science; PsycINFO (OVID); SCOPUS and ERIC (EBSCO) databases was carried out on 15th December 2020. The search terms used across all four databases are outlined in Table 1 and were confined to peer reviewed journal articles. Ancestral and citation searches were also conducted on articles selected for inclusion in the review.

Table 1: Search terms used in this systematic literature review

<td>This review is interested in school-based attribution retraining interventions carried out on school-aged children</td>
</tr>
<tr>
<td>aggression OR &quot;aggressive behaviour&quot; OR violen* OR hostile</td>
<td>This review is interested in studies measuring outcomes of aggressiveness and hostile attributions</td>
</tr>
</tbody>
</table>

Note: Truncation (*) was used to include endings of root words; speech marks (”) ensure inclusion of exact phrases

Article Screening
Initial database searches, as well as ancestral and citation searches, yielded 216 results. After removing 27 duplicates, title and abstract screening was carried out on 189 studies to determine eligibility for inclusion in the review. At this stage the inclusion and exclusion criteria (see Table 2) were applied, and a further 174 records were excluded, leaving 15 articles for ‘full-text’ screening. Ten studies were removed at this stage (see Appendix A), leaving five studies eligible for review (see Table 3). This process is outlined in Figure 1 in the form of a flow diagram.

### Relationship between participation in an AR intervention in a school and changes in aggression

**7. Language**
- Published in the English language
- Not published in the English language

**8. Type of Publication**
- Peer reviewed journal articles
- Grey literature and non-peer reviewed literature

**9. Outcomes**
- Must measure children’s aggression
- Outcome measures not related to aggression

**10. Publication Date**
- The article is published on or before 15th December 2020
- The article is published after 15th December 2020

---

*a* The nature of AR is evaluated in Weight of Evidence C; if a study explicitly claimed its intervention involved AR, it met the inclusion criterion.

*b* The type of aggression is not specified in the inclusion criterion as there are a variety of definitions used in the literature.

Mapping the Field

In order to be included, the reviewed studies all needed to be randomised control trials (RCTs). This is because Petticrew and Roberts (2003) stated that this was the most reliable research design for assessing the effectiveness of an intervention such as AR. Despite having similar research designs, all studies varied in relation to their participant inclusion criteria, outcome measures, intervention duration and delivery.
Weight of Evidence (WoE)

In order to effectively evaluate the quality and relevance of the studies identified, Gough’s (2007) Weight of Evidence (WoE) framework was used, which considers: the methodological quality (WoE A), methodological relevance (WoE B) and topic relevance (WoE C) of each study.

An adapted version of Gersten et al.’s (2005) coding protocol was used to assess methodological quality (WoE A) as it was designed for use with studies that employ group experimental designs.

The author used Petticrew and Roberts (2003) ‘typology of evidence’ to develop a protocol which analysed the strengths and weaknesses of each study’s methodological relevance (WOE B).

A protocol designed by the author was used for WoE C, to assess each study’s topic relevance in relation to the review question. It specifically considered: the intervention focus; the outcome measures; the intervention setting; intervention implementation and the instructor used for each study.

WoE A, B and C were given equal weighting and the sum of these were averaged and rounded to the nearest whole number to give an overall Weight of Evidence D (WoE D). This indicates the strength of evidence in each study in relation to the research question posed. A summary of WoE ratings for each study is outlined in Table 4.

The criteria and rationale for all WoE ratings are outlined in Appendix B. The adapted Gersten et al.’s (2005) coding protocol is outlined in Appendix C, with rationale for changes, and completed examples of the WoE A, B and C coding protocols are given in Appendix D.

Note: WoE ratings are described as: 'High' = 3; 'Medium' = 2; and 'Low' = 1. WoE A, B and C were given equal weighting and the sum of these were averaged and rounded to the nearest whole number to give an overall Weight of Evidence D (WoE D).

Participants

243 participants were included across the five studies. Each study varied in sample size, ranging from 34 participants (Vassilopoulos et al., 2015) to 89 participants (Hudley et al., 1998). The age of participants also varied from 8-16, with two studies focusing on primary age students (Hudley et al., 1998; Hudley & Graham, 1993); two focusing on middle-school aged children (Vassilopoulos et al., 2015; Abdulmalik et al., 2016) and one focusing on secondary aged children (Van Bockstaele et al., 2020). Participants were male only in all but one study (Vassilopoulos et al., 2015).
Participants were identified as aggressive from a variety of peer sociometric nominations and teacher rating scales across all five studies with three studies also including non-aggressive participants (Hudley & Graham, 1993; Hudley et al., 1998; Vassilopoulos et al., 2015) in order to reduce any perceived stigma from participants being involved in the intervention. In these studies, the non-aggressive participants’ data was removed from subsequent analyses. All included studies reported that there were no significant differences between the intervention and control groups in relation to age, gender, or emotion reaction estimates. Participants across the five studies had a variety of ethnic backgrounds and were based in different geographical locations. These include: Greece (White European) (Vassilopoulos et al., 2015); America (African-American and Latino) (Hudley et al., 1998); Holland (White European) (Van Bockstaele et al., 2020); America (African-American) (Hudley & Graham, 1993); and Nigeria (Black African) (Abdulmalik et al., 2016).

**Setting**

In all five studies, the intervention was delivered in schools, as per the inclusion criteria. One study took place within a classroom setting (Abdulmalik et al., 2016) with the remainder carried out elsewhere in the school. This was taken into consideration in the WoE C for setting with Abdulmalik et al.’s (2016) study receiving a higher weighting compared to the other studies. This is because carrying out the intervention within the classroom better enables participants to generalise the skills they have learnt in the intervention to the wider school environment. However, because a specific subset of students had been chosen across a number of different year groups, they were unlikely to be educated within the same class. Therefore, the remaining four studies were given ‘medium’ weightings as withdrawing students for targeted interventions like AR is typical in a school context.
**Research Design**

Randomised controlled trials (RCTs) are considered the most appropriate research design for ‘effectiveness’ questions (Petticrew & Roberts, 2003) and so were in this review’s inclusion criteria. The design used in each study was evaluated using the WoE A and B ratings. All of the studies were RCTs, so received a high WoE B.

All of the studies had an AR experimental group and four of the studies had a test-retest control group (Hudley et al., 1998; Hudley & Graham, 1993; Vassilopoulos et al., 2015; Van Bockstaele et al., 2020). The fifth study had a wait-list control group (Abdulmalik et al., 2016). The existence of a ‘no-intervention’ condition decreased the likelihood that the positive effects observed were due to factors external to the experimental condition (Barker et al., 2015). However, it may have been useful to have an ‘active’ control condition across all five studies as well so that the comparative benefits of the AR intervention could be assessed relative to other aggression-reducing interventions.

Once the sample was derived, the participants were randomly allocated to either the experimental or control group. The use of random allocation reduces the likelihood of selection bias and allows for a direct comparison to occur between conditions. It also ensures that the data demonstrates a more valid representation of how the wider population would respond to AR (Barker et al., 2015), which justifies the high WoE B rating this type of design, and the studies in this review, received.

**Intervention Analysis**

Each study varied in terms of the number of sessions; the length of the intervention; the group size; the intervention program and the outcome measures used, as can be seen in Table 5. The content of each intervention is summarised in Table 6.
The intervention content, implementation and outcome measures will be explored in more detail over the next two sections.

**Intervention Content and Implementation**

As can be seen in Tables 5 and 6 below, each study differed in terms of intervention content and implementation.

Three out of the five studies (Vassilopoulos et al., 2015; Hudley et al., 1998; Van Bockstaele et al., 2020) provided only the title of the instructor with no other details about their background, training or experience, which lowered their scores within both the WoE A and C ratings. The remaining two provided detailed information on the instructor and so were awarded a higher score, which improved their overall WoE A rating. However, Abdulmalik et al. (2016) did not use a teacher to implement the AR intervention therefore still received a rating of 2 for WoE C.

In addition to this, two out of the five studies (Hudley et al., 1993; Abdulmalik et al., 2016) did not provide sufficient information about the intervention content and implementation in order to enable replicability, which lowered their scores within their WoE A rating. The remaining three studies either used a recognised program, which they referenced, or provided sufficient information for replicability and so gained a higher score within the WoE A rating for intervention implementation.

In terms of WoE C, all studies, except Abdulmalik et al. (2016), used solely AR interventions and therefore received a WoE C rating of 3 for the category ‘interventions’. Abdulmalik et al. (2016) received a 2 as in this study it was combined with problem-solving and calming techniques, which made it harder to identify whether it was the AR or the other aspects which led to a reduction in aggression.
The intervention took place in a school in all of the included studies, however, only Abdulmalik et al. (2016) intervention took place in a classroom therefore all of the studies received a WoE C of 2 for ‘setting’ except Abdulmalik et al. (2016), which received a 3. This is because it was thought generalisability would more likely to be achieved within a classroom environment.

Finally, WoE C also looked at ‘implementation’ of the AR intervention. In the Vassilopoulos et al. (2015); Van Bockstaele et al. (2020) and Abdulmalik et al. (2016) studies the intervention only involved direct attributional feedback and so these studies were given a WoE C rating of 2 for ‘implementation’. As the Hudley and Graham (1993) and Hudley et al. (1998) studies used interventions, which included direct attributional feedback, instruction, practice and consolidation, these were given a WoE C of 3 for ‘implementation’ as it is felt these are more likely to be effective in reducing aggression.

</table>
10 scenarios were presented in each of the 5 sessions (50 scenarios in total). The 10 scenarios consisted of: 7 scenarios presented in writing and aurally; 2 scenarios also accompanied by pictures and one was presented as a video fragment. Adaptations were made to assist participants understanding. After the 10 scenarios were presented, a self-paced break was given.

Lesson 1: Not specified

Lessons 2-6: Strengthen ability to accurately detect others' intentions (variety of activities)

Lessons 7-9: Students taught to associate causally ambiguous situations as accidental

Lessons 10-11: Activity linking non-aggressive behavioural responses to ambiguously caused, negative social outcomes

Lesson 12: Not specified

Focused on peer-directed social behaviour and used familiar playground situations appropriate for age of participants.

Lesson 1: Introduction to programme and worked on motivational strategies to support engagement

Session 2: Taught students calming techniques

Session 3: Covered problem-solving strategies

Session 4 and 5: Attribution retraining: specifically focusing on distinguishing between wilful and accidental intent, and recognising ambiguity in interpersonal interactions

Session 6: Recap salient points
Outcome Measures

As can be seen in Table 5, each study assessed attribution and aggression, using different outcome measures, both pre- and post-assessment, with only one study carrying out a follow-up assessment at 12 months (Hudley et al., 1998). Vassilopoulos et al. (2015) used The Aggression Scale (Orpinas & Frankowski, 2001) to measure the degree to which participants engage in overt aggression. It has good psychometric characteristics (Cronbach’s alpha = .83 and .88 pre- and post-assessment) and correlated with teacher ratings $r=0.4$ $p<0.001$. The attribution measure was created by the author for the purpose of the study and had moderate to high internal consistency pre- and post-intervention. Use of standardised measures contributed to this study’s high WoE A and C for outcome measures.

Teachers rated students’ aggression using the teacher version of the Social Skills Rating System (Gresham & Elliot, 1990) in Hudley et al.’s (1998) study. The psychometric properties for this scale are very good. The coefficient reliability for the self-control subscale is .91, and the test-retest reliability coefficient is .80. A student attribution task was created by the authors for the purpose of this study, based on research by Graham et al. (1992), which showed that this was a reliable method of discriminating between aggressive and non-aggressive people. As a result, this study had a high WoE A and C score for outcome measures.

A Dutch translation of the Reactive Proactive Questionnaire (RPQ) (Cima et al., 2013) was used in Van Bockstaele et al.’s (2020) study and this was adapted to a four-point Likert scale, as opposed to the five-point Likert scale that is typical, due to experimenter error. They also included a hostile attribution bias assessment, which
is a variant of the interpretation recognition task (Houtkamp, et al., 2017). The weaknesses associated with the outcome measures used in this study were balanced by other strengths in relation to the intervention content and delivery (outlined above), which led to an overall high WoE A and C for outcomes.

Hudley et al. (1993) used a variety of measures to assess aggression (see Table 5), and, whilst none of the outcome measures in this study had been standardised, the use of multiple measures allowed for triangulation of data, which gave this study a high WoE A rating. As standardised measures were not used in this study, this lowered the WOE C rating for outcomes to 2.

In Abdulmalik et al.’s (2016) study, the author created the following outcome measures for the purpose of the study: a teacher assessment of aggression (qualitative observation); the teacher rating of students’ aggressive behaviour (TRAB); a self-rated aggression scale (SRAS); and a social cognition and attribution scale (SCAS). Abdulmalik et al. (2016) also asked teachers to complete the Strengths and Difficulties questionnaire (SDQ) (Goodman, 2001). The use of multiple measures allowed for triangulation of data, however, insufficient information was provided on intervention content and implementation therefore this study achieved a low WoE A rating. Despite this, as a standardised measure was used in this study and triangulation of data was possible, the study was given a WOE C rating of 3 for outcomes.
Findings

Outcome and Effect Size

As the focus of this review was on the effects of AR on aggression, only effect sizes on general measures of aggression were reported. A summary of each study’s effect sizes along with their main findings are summarised in Table 7 with the effect size descriptors outlined in Table 8. Cohen’s d was extracted from one study (Van Bockstaele et al., 2020), whilst partial eta squared was extracted from a further study (Vassilopoulos et al., 2015) and converted into Cohen’s d using the Psychometrica calculator (Lenhard & Lenhard, 2016) to enable comparison. The effect size was not quoted in the remaining studies so it was calculated using the F-statistic of the interaction between pre- and post- scores and the AR intervention and control groups using the Campbell Collaboration Online calculator (Wilson, n.d.).

All studies reported a large effect size, suggesting school-based AR interventions reduce aggression in school-age populations. This is in line with previous research that demonstrated the positive effect of AR on aggression (Graham, 1997). As all five studies reported no significant differences between groups, and all of the studies presented with methodologically sound effect sizes for the specified population, a meta-analysis was carried out to assess the overall effect of AR on aggression.

assessments were carried out so the long-term effect of AR is unclear.

Hudley & Graham (1993) Aggressive participants in the AR intervention group were less likely to presume hostile intent from peers in hypothetical and lab-based simulations of ambiguous provocation post-intervention. Further to this, participants were rated as less aggressive in teacher feedback following the interventions completion. The authors did not carry out any follow-up assessments so the long-term effect of AR is unclear.

Abdulmalik et al. (2016) The AR intervention group had significantly lower teacher rating of aggressive behaviour and lower ratings on the self-rated aggression scale, 1-week post intervention. The authors reported that this demonstrated that the incidence of aggressive behaviours in the AR group had decreased relative to the control group. The authors did not carry out any follow-up assessments so the long-term effect of AR is unclear.

Meta-analysis

The meta-analysis was conducted using a random-effects model in Meta-Essentials software (Suurmond et al., 2017). A random-effects model was used due to the heterogeneity across studies in terms of the participants and intervention, meaning that there may be a range of ‘true’ effect-sizes (Borenstein et al., 2010). The comparison group in the meta-analysis was the control group in each study. The control groups in each study did not experience any intervention and so provide a useful contrast to the intervention group. A summary of effect sizes and meta-analysis parameters is provided in Table 9 with a Forest plot included in Figure 2.

For the purposes of the meta-analysis, Cohen’s d was calculated using the pooled standard deviation from both groups and corrected for small sample upward-bias, yielding an overall effect across all studies of $g = 1.01$ (95% CI$_{lower}$=0.79, CI$_{upper}$=1.23). This represents a large overall effect in favour of AR interventions, according to Cohen’s criteria. This is indicative of the large effect size that each study had. These correspond with high WoE D ratings in four of the studies with the exception being Abdulmalik et al. (2016), which received a medium WoE D. This means that more caution should be given when reporting the accuracy of this study’s results.

Hudley et al. (1998)
Van Bockstaele et al. (2020)
Hudley & Graham (1993)
Abdulmalik et al. (2016)
Combined effect size
As well as having a significantly large overall effect size, there was low heterogeneity in the findings (Cochran’s Q=1.41, p=0.842, I²=0.00%, t²=0). Accordingly, this indicates that the effect of the intervention is not highly variable between studies and so recommendations can be made based on the findings of this review.

Conclusions and Recommendations

Discussion of Findings

This review evaluated the effectiveness of school-based AR interventions in reducing peer-directed aggressive behaviour in children. Five studies met the inclusion criteria, with four receiving a high WoE D rating and one receiving a medium WoE D rating.

Combining the evidence of statistical effect, methodological quality, and methodological and topical relevance, it can be concluded that school-based AR interventions had a large effect on reducing peer-related aggression in aggressive children. Gersten et al. (2005) proposes that there needs to be at least two studies with high WoE A and a combined effect size significantly greater than zero for an intervention to be classified as ‘evidence-based practice’. As four of the studies within this review had high WoE A ratings and the combined effect size was g=1.01, this review demonstrates an evidence base for the effectiveness of school-based AR interventions in reducing aggression in school aged populations.

It cannot, however, be concluded that the effects of AR are long-term as only one study assessed effectiveness 12 months post-intervention and the treatment effects had significantly reduced during this time, though to a lesser degree in the experimental group than the control group (Hudley et al. 1998). In addition, it cannot be concluded that this is the most effective intervention for reducing aggression. This
is because all of the studies had a no-intervention comparison group, meaning comparison between AR and other interventions was not possible.

Limitations of the Review

It could be argued that this review’s inclusion criteria included studies which implemented AR interventions in a wide variety of formats, alongside utilising various outcome measures, which may have impacted the comparability of these studies. However, this was taken into consideration in WoE C and a random-effects meta-analysis was carried out in order to try to mitigate the impact of this.

The author of this review also developed their own protocol for WoE C, which was necessary due to the specificity of the review question and lack of existing protocols in this field. However, this could be questioned as it was not possible to test it for construct or inter-rater reliability prior to review submission.

Recommendations for Future Research

Given, the lack of UK-based research on the effectiveness of AR interventions on aggression in school-aged children, the extent to which this approach could be modified for the UK education system could be an area for future research.

In addition, the long-term benefits of AR interventions are unclear and were only investigated by one study. Therefore, further studies could include follow-up measures to evaluate maintenance and generalisability of effect.

Recommendations for Practice

EPs have an ethical responsibility to ensure that any interventions they recommend have a current and sound evidence base (BPS, 2018). As this review demonstrates an evidence base for school-based AR interventions, EPs may consider
recommending it to schools where there is a concern about aggressive behaviour. This is important given the damaging effect aggressive behaviour can have on the long- and short-term outcomes for children.

Despite this, none of the studies were carried out in the UK and therefore, it is unclear whether the results are generalisable to the UK school population, given its cultural disparity and the different schooling systems. This may impact upon EPs’ confidence in recommending AR, without further UK-based evidence. In addition, the findings of this review suggest that the effectiveness of AR interventions decreased over time, which may give EPs further reservations.

Despite this, within the current review, results did replicate between different countries, languages and school systems. Therefore, it may be inferred that similar results would be found within a UK sample. In addition, only one study in this review conducted follow-up assessments and therefore it is not possible to make robust conclusions without further research on long-term impact.

Overall, given the benefits of school-based AR interventions for aggressive school children, it should be seriously considered for use by EPs, with a view that further research could be carried out to explore the UK context and longer-term effects.

Criteria and rationale for all Weight of Evidence (WoE) Ratings

WoE A: Methodological Quality

WoE A enables the user to judge whether a study has been well executed (Gough, 2007). The Gersten et al. (2005) coding protocol was used to analyse all five studies as it is designed to evaluate group experimental designs, such as the RCTs in this review. This coding protocol includes both essential and desirable criteria. Adjustments were made to some of the questions within this protocol and are outlined in Appendix C with rationale. The criteria weighting for each WoE A rating is provided in Table B1 below. A summary of scores for each study is provided in Table B2. A completed example of a WoE A protocol is provided in Appendix D.

**Note:** WoE ratings are described as: ‘High’ = 3; ‘Medium’ = 2; and ‘Low’ = 1.
WoE B: Methodological Relevance

WoE B enables the quality and relevance of the research design of the studies in this review to be judged relative to the review question (Gough, 2007). For this review, WoE B considered the relevance of the methodology for evaluating the effectiveness of AR interventions in reducing peer-related aggression in school-based settings.

The coding protocol for WoE B was developed by the author and based on Petticrew and Roberts (2003) ‘typology of evidence’. This enabled the author to analyse the strengths and weaknesses of each study’s methodological approach relative to the question of ‘effectiveness’ in this review. Petticrew and Robert's (2003) findings on the type of studies most suited for ‘effectiveness’ questions and the criteria allocated for ‘low’ (1), ‘medium’ (2) and ‘high’ (3) ratings are outlined in table B3 below along with the rating for each study. A completed example of a WoE B protocol is provided in Appendix D.

Note: WoE ratings are described as: ‘High’ = 3; ‘Medium’ = 2; and ‘Low’ = 1.
WoE C: Topic Relevance

Weight of Evidence C (WoE C) evaluates the relevance of the focus of the study relative to the review question. Studies were rated on five areas: intervention, outcomes, setting, implementation and instructors, and the criteria are outlined in more detail below along with the rationale (see Table B4). The WoE C ratings for each study are outlined in Table B5 and a completed example of a WoE C protocol is provided in Appendix D.

Table B4 Criteria and Rationale for WoE C Ratings

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Rating</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. Intervention</td>
<td>3-</td>
<td>AR is the sole intervention or the primary feature of the main intervention.</td>
</tr>
<tr>
<td></td>
<td>2-</td>
<td>AR is combined with another intervention or adapted in a minor way, which does not impact the fidelity of the AR aspect of the intervention being carried out.</td>
</tr>
<tr>
<td></td>
<td>1-</td>
<td>Attribution retraining is not a core feature of the intervention.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>It is important to understand how effective AR was in the intervention condition. As a result, any studies which do not have AR as the main component will be excluded.</td>
</tr>
<tr>
<td>B. Outcomes</td>
<td>3-</td>
<td>Outcomes measured using a standardised assessment of aggression</td>
</tr>
<tr>
<td></td>
<td>2-</td>
<td>Outcomes are not measured using a standardised assessment of aggression.</td>
</tr>
<tr>
<td></td>
<td>2-</td>
<td>Multiple non-standardised measures such as an instructor constructed assessment of aggression and/or peer rating scale(s) have been used</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Outcome measures must accurately assess the effect AR has on aggression. Standardised measures can provide a more accurate portrayal but use of multiple measures allows for triangulation which can improve the accuracy of results.</td>
</tr>
</tbody>
</table>
1- Outcomes measures indirectly assess aggression e.g. hostile attribution bias, anger.

C. Setting
3 The intervention was conducted in a classroom setting within the school the participant is attending
2- The intervention was carried out in a separate location within the school the participant is attending
1- The intervention was carried out in a non-school setting e.g. clinic

In order for results to be generalisable, the ideal location for the intervention would be in the classroom. However, within the same school could still be beneficial in this respect. Studies which conducted AR interventions outside of school have been excluded as this review is looking at school-based interventions.

D. Implementation
3- The intervention is multi-faceted and involves a variation of instruction, practice, direct attributional feedback and consolidation work.
2- The intervention provides direct attributional feedback only.
1- The intervention provides indirect attributional feedback.

AR interventions can vary in terms of their implementation, however, the more rigorous and multi-faceted the approach the more likely it is to be effective.

E. Instructor
3- The intervention is delivered by an AR-trained member of staff at the school the participant is attending
2- The intervention is delivered by an AR-trained researcher
1- The intervention is delivered by an individual with minimal AR-training

It is thought the more familiar the instructor the more successful and generalisable the intervention is likely to be. In addition, it is thought that the more rigorous the training of the instructor, the greater the fidelity of the intervention implementation. If the instructor is untrained, the intervention is less likely to be effective in AR.

Nota: WoE ratings are described as: ‘High’ = 3; ‘Medium’ = 2; and ‘Low’ = 1. Each Criteria Rating were given equal weighting and the sum of these were averaged and rounded to the nearest whole number to give an overall Weight of Evidence C (WoE C)
Weight of Evidence D (WoE D): Overall Weight of Evidence

WoE D provides a judgement of the overall weight of evidence for each study and is calculated by averaging the ratings from WoE A, B and C for each study. This overall rating is important as it specifies the extent to which each study has contributed evidence towards the review question. The WoE D for each study is outlined in Table B6.

Note: WoE ratings are described as: ‘High’ = 3; ‘Medium’ = 2; and ‘Low’ = 1. WoE A, B and C were given equal weighting and the sum of these were averaged and rounded to the nearest whole number to give an overall Weight of Evidence D (WoE D).
Appendix C

Adaptations made to the WoE A coding protocol (Gersten et al., 2005)

Changes were made to Gersten et al.’s (2005) coding protocol to improve the clarity of the text and ensure it was appropriate for the review question posed. Deletions are shown by strikes through the text, additional text is in {curly brackets}, and the rationale for the changes are written in [square brackets]. All other text is the same as the original. As a result of these changes, there were ten desirable criteria rather than the original 8. The criteria of Gersten et al. (2005) for a ‘high’ quality study were altered to require 5, rather than 4, desirable criteria and this is shown in Table B1 above.

Essential Quality Indicators

Quality indicators for describing participants

Was sufficient information provided to determine/confirm whether the participants demonstrated the disability(ies) or difficulties presented?

[Rationale: ‘difficulties’ is more appropriate terminology than ‘disabilities’ in relation to the concept of aggression]

Were appropriate procedures used to increase the likelihood that relevant characteristics of participants in the sample were comparable across conditions?

Was sufficient information given characterizing the interventionists {instructors} or teachers provided? Did it indicate whether they were comparable across conditions?
[Rationale: change of ‘interventionists’ to ‘instructors’ to ensure consistency in the language used throughout this review]

**Quality indicators for implementation of the intervention and description of comparison conditions**

- Was the intervention clearly described and specified?
- Was the fidelity of implementation described and assessed?
- Was the nature of services provided in comparison conditions described?

**Quality indicators for outcome measures**

- Were multiple measures used to provide an appropriate balance between measures closely aligned with the intervention and measures of generalised performance?
- Were outcomes for capturing the intervention’s effect measured at the appropriate times?

**Quality indicators for data analysis**

- Were the data analysis techniques appropriately linked to key research questions and hypotheses? Were they appropriately linked to the unit of analysis in the study?
- Did the research report include not only inferential statistics but also effect size calculations?

**Desirable Quality Indicators**

- Was data available on attrition rates among intervention samples? Was severe overall attrition documented? If so, is attrition comparable across samples? Is overall attrition less than 30%?
{Was severe overall attrition (30% or more) avoided? Is attrition comparable across samples?}

[Rationale: It was possible that some studies may meet the first part of the criteria but would still be coded negatively if they did not meet the second part, therefore the questions were split into two parts to allow for each to be graded separately (see {...} above for additional question)]

Did the study provide not only internal consistency reliability but also test-retest reliability and interrater reliability (when appropriate) for outcome measures? Were data collectors and/or scorers blind to study conditions and equally (un)familiar to examinees across study conditions?

{Were data collectors and/or scorers blind to study conditions and equally (un)familiar to examinees across study conditions?}

[Rationale: It was possible that some studies may meet the first part of the criteria but would still be coded negatively if they did not meet the second part, therefore the questions were split into two parts to allow for each to be graded separately (see {...} above for additional question)]

Were outcomes for capturing the intervention’s effect measured beyond an immediate post-test?

Was evidence of the criterion-related validity and construct validity of the measures provided?

Did the research team assess not only surface features of fidelity implementation (e.g. number of minutes allocated to the intervention or teacher/interventionist following procedures specified), but also examine quality of implementation?
Was any documentation of the nature of instruction or series provided in comparison conditions?

Did the research report include actual (written,) audio or videotape excerpts that capture the nature of the intervention?

[Rationale: It would be possible for a study to capture the nature of the intervention in written form with similar levels of ecological validity to audio or videotape excerpts therefore it was deemed that this should be included as a further option]

Were results presented in a clear, coherent fashion?

Overall Rating of Evidence: □3 □2 □1 □0
Appendix D

Example of a completed WoE A coding protocol from one study

Coding protocol:

Study 1: Vassilopoulos et al. (2015)

**Essential Quality Indicators**

**Quality indicators for describing participants**

Was sufficient information provided to determine whether the participants demonstrated the difficulties presented?
- ☑ Yes
- ☐ No
- ☐ Unknown/Unable to Code

Were appropriate procedures used to increase the likelihood that relevant characteristics of participants in the sample were comparable across conditions?
- ☐ Yes
- ☑ No
- ☐ Unknown/Unable to Code

Was sufficient information given characterizing the instructors or teachers provided? Did it indicate whether they were comparable across conditions?
- ☐ Yes
- ☑ No
- ☐ Unknown/Unable to Code

**Quality indicators for implementation of the intervention and description of comparison conditions**

Was the intervention clearly described and specified?
- ☑ Yes
- ☐ No
- ☐ Unknown/Unable to Code
Was the fidelity of implementation described and assessed?
☑ Yes
☐ No
☐ Unknown/Unable to Code

Was the nature of services provided in comparison conditions described?
☑ Yes – test-retest – no intervention condition
☐ No
☐ Unknown/Unable to Code

**Quality indicators for outcome measures**

Were multiple measures used to provide an appropriate balance between measures closely aligned with the intervention and measures of generalised performance?
☑ Yes
☐ No
☐ Unknown/Unable to Code

Were outcomes for capturing the intervention’s effect measured at the appropriate times?
☑ Yes – pre and post assessment
☐ No
☐ Unknown/Unable to Code

**Quality indicators for data analysis**

Were the data analysis techniques appropriately linked to key research questions and hypotheses? Were they appropriately linked to the unit of analysis in the study?
☑ Yes
☐ No
☐ Unknown/Unable to Code

Did the research report include not only inferential statistics but also effect size calculations?
☑ Yes – partial eta squared = .18 equates to Cohen’s d = 0.94
☐ No
☐ Unknown/Unable to Code
**Desirable Quality Indicators**

Was data available on attrition rates among intervention samples?
- ☑ Yes – assume no one left the study based on N reported in results being same as in methods section
- ☐ No
- ☐ Unknown/Unable to Code

Was severe overall attrition (30% or more) avoided? Is attrition comparable across samples?
- ☑ Yes
- ☐ No
- ☐ Unknown/Unable to Code

Did the study provide not only internal consistency reliability but also test-retest reliability and interrater reliability (when appropriate) for outcome measures?
- ☑ Yes
- ☐ No
- ☐ Unknown/Unable to Code

Were data collectors and/or scorers blind to study conditions and equally (un)familiar to examinees across study conditions?
- ☐ Yes
- ☐ No
- ☑ Unknown/Unable to Code

Were outcomes for capturing the intervention’s effect measured beyond an immediate post-test?
- ☐ Yes
- ☑ No
- ☐ Unknown/Unable to Code

Was evidence of the criterion-related validity and construct validity of the measures provided?
- ☐ Yes
- ☑ No
- ☐ Unknown/Unable to Code
Did the research team assess not only surface features of fidelity implementation (e.g. number of minutes allocated to the intervention or teacher/interventionist following procedures specified), but also examine quality of implementation?

☐ Yes
☒ No
☐ Unknown/Unable to Code

Was any documentation of the nature of instruction or series provided in comparison conditions?

☒ Yes – no intervention control group – test-retest
☐ No
☐ Unknown/Unable to Code

Did the research report include actual written, audio or videotape excerpts that capture the nature of the intervention?

☒ Yes – written examples of materials used
☐ No
☐ Unknown/Unable to Code

Were results presented in a clear, coherent fashion?

☒ Yes
☐ No
☐ Unknown/Unable to Code

Overall Rating of Evidence:  ☒ 3  ☐ 2  ☐ 1  ☐ 0
Example of a completed WoE B coding protocol from one study

Coding protocol:
Created for the purposes of this review. Criteria rationale based on “Typology of evidence” recommendations for research best suited to studying the effectiveness of interventions (Petticrew and Roberts, 2003).

Study 1: Vassilopoulos et al. (2015)

Criteria WoE B Rating Criteria 3
Randomised Controlled trials (RCTs)
At least one control/comparison group

Criteria WoE B Rating Criteria 2
Cohort studies or Quasi-experimental studies (non-random assignment):
At least one control/comparison group

Criteria WoE B Rating Criteria 1
Research that collects qualitative data, surveys, non-experimental studies:
No control/comparison group

Overall Rating of Evidence: ★ 3    □  2    □  1    □  0
Example of a completed WoE C coding protocol from one study

Coding protocol:
Created for the purposes of this review.

Study 1: Vassilopoulos et al. (2015)

A. Intervention
3- Attribution retraining is the primary intervention or the core feature of the main intervention condition.
2- Attribution retraining is combined with another intervention.
1- Attribution retraining is the secondary or tertiary intervention.

As many studies combine attribution retraining with other interventions, it is important to understand how significant of a feature attribution retraining was in the intervention condition.

B. Outcomes
3- Outcomes have been measured using a standardised assessment of aggression.
2- Outcomes have been measured using a teacher/instructor constructed assessment of aggression and peer rating scale.
1- Outcomes have been measured using an assessment that indirectly measures aggression.

This question focuses on the effect of attribution retraining on aggression, so outcome measures must accurately measure this. Standardised and/or validated measures will produce a more accurate portrayal.

C. Setting
3 The intervention was conducted in a classroom setting.
2- The intervention was carried out in a separate location within a school.
1- The intervention was carried out in a non-school setting such as a psychology lab or office.

As the intervention is intended to be used in school, the study should also take place in a realistic school setting in order for results to be generalisable.
D. Implementation

3- The intervention involves direct attributional feedback, instruction, practice and consolidation.

2- The intervention involves direct attributional feedback.

1- The intervention involves indirect attributional feedback through modelling, face-to-face or via video.

Attribution retraining does not have clear implementation guidelines but it does contain some key elements that should be included. The level of which these features are included will impact how closely the study reflects how attribution retraining will be implemented in practice.

E. Instructor

3- The intervention is delivered by a member of the teaching staff who has been trained in Attribution Retraining.

2- The intervention is delivered by a researcher who has been trained in Attribution Retraining.

1- The intervention is delivered by an individual who has received minimal training in Attribution Retraining.

The intervention is intended to be delivered in schools and by trained school staff, so if the study does so it will more closely reflect how Attribution Retraining will be implemented in practice. If the instructor is untrained in Attribution Retraining then the intervention is unlikely to be effective in retraining attributions.

Overall Rating of Evidence: □ 3 □ 2 □ 1 □ 0
