Fundamentals of Magnetohydrodynamics (MHD)

Tony Arber

University of Warwick

STFC Advanced School, MSSL September 2013.
Aim

Derivation of MHD equations from conservation laws
Quasi-neutrality
Validity of MHD
MHD equations in different forms
MHD waves
Alfven’s Frozen Flux Theorem
Line Conservation Theorem
Characteristics
Shocks

Applications of MHD, i.e. all the interesting stuff!, will be in later lectures covering Waves, Reconnection and Dynamos etc.
Possible to derive MHD from
• N-body problem to Klimotovich equation, then take moments and simplify to MHD
• Louiville theorem to BBGKY hierarchy, then take moments and simplify to MHD
• Simple fluid dynamics and control volumes

First two are useful if you want to study kinetic theory along the way but all kinetics removed by the end

Final method followed here so all physics is clear
Ideal MHD

\[
\frac{\partial \mathbf{B}}{\partial t} = -\nabla \wedge \mathbf{E}
\]

\[
\frac{\partial \rho}{\partial t} + \nabla.(\rho \mathbf{v}) = 0
\]

\[
\rho \frac{d\mathbf{v}}{dt} = -\nabla p + \mathbf{j} \times \mathbf{B}
\]

\[
\nabla \wedge \mathbf{B} = \mu_0 \mathbf{j}
\]

\[
\frac{d}{dt} \left( \frac{p}{\rho^\gamma} \right) = 0
\]

\[
\mathbf{E} + \mathbf{v} \wedge \mathbf{B} = 0
\]

Maxwell equations

Mass conservation

F = ma for fluids

Low frequency Maxwell

Adiabatic equation for fluids

Ideal Ohm’s Law for fluids

8 equations with 8 unknowns
Mass $m$ in cell of width $\Delta x$ changes due to rate of mass leaving/entering the cell $F(x)$

$$\frac{\partial}{\partial t} \left( \int_x^{x+\Delta x} \rho \, dx \right) = F(x) - F(x + \Delta x)$$

$$\frac{\partial \rho}{\partial t} = \lim_{\Delta x \to 0} \frac{F(x) - F(x + \Delta x)}{\Delta x}$$

$$\frac{\partial \rho}{\partial t} + \frac{\partial F(x)}{\partial x} = 0$$
Mass flux - conservation laws

\[ \frac{\partial \rho}{\partial t} + \frac{\partial F(x)}{\partial x} = 0 \]

Mass flux per second through cell boundary

\[ F(x, t) = \rho(x, t) \ v_x(x, t) \]

In 3D this generalizes to

\[ \frac{\partial \rho}{\partial t} + \nabla.(\rho \mathbf{v}) = 0 \]

This is true for any conserved quantity so if \( \int \mathbf{U} \ dx \) conserved

\[ \frac{\partial \mathbf{U}}{\partial t} + \nabla.\mathbf{F} = 0 \]

Hence applies to mass density, momentum density and energy density for example.
In fluid dynamics the relation between total and partial derivatives is

\[
\frac{d}{dt} = \frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla
\]

**Convective derivative:**
Rate of change of quantity at a point moving with the fluid.

Often, and frankly for no good reason at all, write

\[
\frac{D}{Dt} \text{ instead of } \frac{d}{dt}
\]
Adiabatic energy equation

If there is no heating/conduction/transport then changes in fluid element’s pressure and volume (moving with the fluid) is adiabatic

\[ PV^\gamma = constant \]

Where \( \gamma \) is ratio of specific heats

\[ \frac{d}{dt} (PV^\gamma) = 0 \]

Moving with a packet of fluid the mass is conserved so \( V \propto \rho^{-1} \)

\[ \frac{d}{dt} \left( \frac{P}{\rho^\gamma} \right) = 0 \]
Momentum equation - Euler fluid

Total momentum in cell changes due to pressure gradient

\[
\frac{\partial}{\partial t} (\rho u_x \Delta x) = F(x) - F(x + \Delta x) + P(x) - P(x + \Delta x)
\]

Now \( F \) is momentum flux per second \( F = \rho u_x u_x \)

\[
\frac{\partial}{\partial t} (\rho u_x) + \frac{\partial F}{\partial x} = -\nabla P
\]
Use mass conservation equation to rearrange as

\[\rho \frac{\partial u_x}{\partial t} + \rho u_x \frac{\partial u_x}{\partial x} = -\nabla P\]

\[\rho \left( \frac{\partial u_x}{\partial t} + u_x \frac{\partial u_x}{\partial x} \right) = -\nabla P\]

\[\rho \frac{du_x}{dt} = -\nabla P\]

Since by chain rule

\[
\frac{du_x(x, t)}{dt} = \frac{\partial u_x}{\partial t} + \frac{\partial x}{\partial t} \frac{\partial u_x}{\partial x}
\]
Momentum equation - MHD

For Euler fluid \( \rho \frac{du}{dt} = -\nabla P \) how does this change for MHD?

Force on charged particle in an EM field is

\[
F = q(E + v \times B)
\]

Hence total EM force per unit volume on electrons is

\[
-n_e e(E + v \times B)
\]

and for ions (single ionized) is

\[
n_i e(E + v \times B)
\]

Where \( n_e \) and \( n_i \) are the electron and ion number densities
Hence total EM force per unit volume

\[ e(n_i - n_e)E + (en_i u_i - en_e u_e) \times B \]

If the plasma is quasi-neutral (see later) then this is just

\[ en(u_i - u_e) \times B = j \times B \]

Where \( j \) is the current density. Hence

\[ \rho \frac{du}{dt} = -\nabla P + j \times B \]

Note \( j \times B \) is the only change to fluid equations in MHD. Now need an equation for the magnetic field and current density to close the system.
**Maxwell equations**

\[ \nabla \cdot \mathbf{E} = \frac{\rho}{\varepsilon_0} \]

Not allowed in MHD!

\[ \nabla \cdot \mathbf{B} = 0 \]

Initial condition only

\[ \nabla \wedge \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t} \]

Used to update \( \mathbf{B} \)

\[ \nabla \wedge \mathbf{B} = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \mathbf{E}}{\partial t} \]

'Low' frequency version used to find current density \( \mathbf{j} \)
Low-frequency Maxwell equations

\[ \nabla \wedge \mathbf{B} = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \mathbf{E}}{\partial t} \]

\[ \varepsilon_0 \mu_0 \frac{E_0}{T} = \frac{1}{c^2} \frac{E_0}{T} \]

Magnitude \( \sim \) \( \frac{\text{typical B}}{\text{length-scale}} \sim \frac{B_0}{L} \)

\[ \left| \varepsilon_0 \mu_0 \frac{\partial \mathbf{E}}{\partial t} \right| \sim \frac{L}{T} \frac{1}{c^2} \frac{E_0}{B_0} \]
Displacement current

\[ \frac{\varepsilon_0 \mu_0}{\nabla \wedge \mathbf{B}} \frac{\partial \mathbf{E}}{\partial t} \sim \frac{L}{T} \frac{1}{c^2} \frac{E_0}{B_0} \]

Later we will show that in MHD \( \frac{E_0}{B_0} \sim V \)

\[ \frac{\varepsilon_0 \mu_0}{\nabla \wedge \mathbf{B}} \frac{\partial \mathbf{E}}{\partial t} \sim \frac{L}{T} \frac{V}{c^2} \sim \frac{V^2}{c^2} \]

So for low velocities/frequencies we can ignore the displacement current
For a pure hydrogen plasma we have

\[
\frac{\partial n_i}{\partial t} + \nabla \cdot (n_i \mathbf{u}_i) = 0 \quad \frac{\partial n_e}{\partial t} + \nabla \cdot (n_e \mathbf{u}_e) = 0
\]

Multiply each by their charge and add to get

\[
\frac{\partial \sigma}{\partial t} + \nabla \cdot \mathbf{j} = 0
\]

where \(\sigma\) is the charge density and \(\mathbf{j}\) is the current density

\[
\mathbf{j} = e n_i \mathbf{u}_i - e n_e \mathbf{u}_e
\]

From Ampere's law

\[
\nabla \times \mathbf{B} = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \mathbf{E}}{\partial t}
\]

if we look only at low frequencies

\[
\nabla \times \mathbf{B} = \mu_0 \mathbf{j} \quad \nabla \cdot (\nabla \times \mathbf{B}) = \mu_0 \nabla \cdot \mathbf{j} \quad \nabla \cdot \mathbf{j} = 0
\]

\[
\frac{\partial \sigma}{\partial t} = 0
\]

Hence for low frequency processes \(n_i \approx n_e\) this is quasi-neutrality
MHD

\[ \frac{\partial \mathbf{B}}{\partial t} = -\nabla \wedge \mathbf{E} \]  
Maxwell equations

\[ \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = 0 \]  
Mass conservation

\[ \rho \frac{d\mathbf{v}}{dt} = -\nabla p + \mathbf{j} \times \mathbf{B} \]  
Momentum conservation

\[ \nabla \wedge \mathbf{B} = \mu_0 \mathbf{j} \]  
Low frequency Maxwell

\[ \frac{d}{dt} \left( \frac{p}{\rho^\gamma} \right) = 0 \]  
Energy conservation

8 equations with 11 unknowns! Need an equation for \( \mathbf{E} \)
Ohm's Law

Equations of motion for ion fluid is

\[ m_i n_i \frac{d\mathbf{u}_i}{dt} = en_i \left( \mathbf{E} + \mathbf{u}_i \wedge \mathbf{B} \right) - \nabla P_i + \mathbf{F}_{ie} \]

Assume quasi-neutrality, subtract electron equation

\[ \frac{m_e}{ne^2} \frac{\partial \mathbf{j}}{\partial t} = \mathbf{E} + \mathbf{v} \wedge \mathbf{B} - \frac{1}{ne} (\mathbf{j} \wedge \mathbf{B}) - \frac{1}{ne} \nabla P_e - \eta \mathbf{j} \]

This is called the generalized Ohm's law

Note that Ohm's law for a current in a wire (V=IR) when written in terms of current density becomes \( \mathbf{E} = \eta \mathbf{j} \)

When fluid is moving this becomes \( \mathbf{E} + \mathbf{v} \wedge \mathbf{B} = \eta \mathbf{j} \)
Magnetohydrodynamics (MHD)

\[ \frac{\partial \mathbf{B}}{\partial t} = -\nabla \wedge \mathbf{E} \]

\[ \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = 0 \]

\[ \rho \frac{d\mathbf{v}}{dt} = -\nabla p + \mathbf{j} \times \mathbf{B} \]

\[ \nabla \wedge \mathbf{B} = \mu_0 \mathbf{j} \]

\[ \frac{d}{dt} \left( \frac{p}{\rho^\gamma} \right) = 0 \]

\[ \mathbf{E} + \mathbf{v} \wedge \mathbf{B} = \eta \mathbf{j} \]

Valid for:

- Low frequency
- Large scales

If \( \eta=0 \) called ideal MHD

Missing viscosity, heating, conduction, radiation, gravity, rotation, ionisation etc.
Validity of MHD

Assumed quasi-neutrality therefore must be low frequency and speeds \( \ll \) speed of light

Assumed scalar pressure therefore collisions must be sufficient to ensure the pressure is isotropic. In practice this means:

- mean-free-path \( \ll \) scale-lengths of interest
- collision time \( \ll \) time-scales of interest
- Larmor radii \( \ll \) scale-lengths of interest

However as MHD is just conservation laws plus low-frequency MHD it tends to be a good first approximation to much of the physics even when all these conditions are not met.
Eulerian form of MHD equations

\[ \frac{\partial \rho}{\partial t} = -\nabla \cdot (\rho \mathbf{v}) \]

\[ \frac{\partial P}{\partial t} = -\gamma P \nabla \cdot \mathbf{v} \]

\[ \frac{\partial \mathbf{v}}{\partial t} = -\mathbf{v} \cdot \nabla (\mathbf{v}) - \frac{1}{\rho} \nabla P + \frac{1}{\rho} \mathbf{j} \times \mathbf{B} \]

\[ \frac{\partial \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B}) \]

\[ \mathbf{j} = \frac{1}{\mu_0} \nabla \times \mathbf{B} \]

Final equation can be used to eliminate current density so 8 equations in 8 unknowns
Lagrangian form of MHD equations

\[
\frac{D\rho}{Dt} = -\rho \nabla \cdot \mathbf{v}
\]

\[
\frac{DP}{Dt} = -\gamma P \nabla \cdot \mathbf{v}
\]

\[
\frac{D\mathbf{v}}{Dt} = -\frac{1}{\rho} \nabla P + \frac{1}{\rho} \mathbf{j} \times \mathbf{B}
\]

\[
\frac{DB}{Dt} = (\mathbf{B} \nabla) \mathbf{v} - \mathbf{B} (\nabla \cdot \mathbf{v})
\]

\[
\mathbf{j} = \frac{1}{\mu_0} \nabla \times \mathbf{B}
\]

Alternatives

\[
\frac{D\epsilon}{Dt} = -\frac{P}{\rho} \nabla \cdot \mathbf{v}
\]

Specific internal energy density

\[
\epsilon = \frac{P}{\rho(\gamma - 1)}
\]

\[
\frac{D}{Dt} \left( \frac{\mathbf{B}}{\rho} \right) = \frac{\mathbf{B}}{\rho} \cdot \nabla \mathbf{v}
\]
Conservative form

\[
\frac{\partial \rho}{\partial t} = -\nabla \cdot (\rho \mathbf{v})
\]

\[
\frac{\partial \rho \mathbf{v}}{\partial t} = -\nabla \cdot \left( \rho \mathbf{v} \cdot \mathbf{v} + \mathbf{I}(P + \frac{B^2}{2}) - \mathbf{B} \mathbf{B} \right)
\]

\[
\frac{\partial E}{\partial t} = -\nabla \cdot \left( \left( E + P + \frac{B^2}{2 \mu_0} \right) \mathbf{v} - \mathbf{B} (\mathbf{v} \cdot \mathbf{B}) \right)
\]

\[
\frac{\partial \mathbf{B}}{\partial t} = -\nabla (\mathbf{v} \mathbf{B} - \mathbf{B} \mathbf{v})
\]

\[
E = \frac{P}{\gamma - 1} + \frac{\rho v^2}{2} + \frac{B^2}{2 \mu_0} \quad \text{The total energy density}
\]
A key dimensionless parameter for ideal MHD is the plasma-beta

It is the ratio of thermal to magnetic pressure

$$\beta = \frac{2\mu_0 P}{B^2}$$

Low beta means dynamics dominated by magnetic field, high beta means standard Euler dynamics more important

$$\beta \propto \frac{c_s^2}{v_A^2}$$
Assume initially in stationary equilibrium

\[ \nabla \cdot P_0 = j_0 \times B_0 \]

Simplify to easiest case with \( \rho_0, P_0, B_0 = B_0 \hat{z} \) constant and no equilibrium current or velocity

Apply perturbation, e.g. \( P = P_0 + P_1 \)
Ignore quadratic terms, e.g. \( P_1 \nabla \cdot \mathbf{v}_1 \)

Linear equations so Fourier decompose, e.g.

\[
P_1(\mathbf{r}, t) = P_1 \exp i(\mathbf{k} \cdot \mathbf{r} - \omega t)
\]

Gives linear set of equations of the form \( \bar{A} \bar{u} = \lambda \bar{u} \)

Where \( \bar{u} = (P_1, \rho_1, v_1, B_1) \)

Solution requires \( \det |\bar{A} - \lambda \bar{I}| = 0 \)
Dispersion relation

\[(\omega^2 - C_A^2 k^2 \cos^2 \alpha)(\omega^2 - C_s^2 k^2) - C_A^2 \omega^2 k^2 \sin^2 \alpha = 0\]

(Fast and slow magnetoacoustic waves)

\[\omega^2 - C_A^2 k^2 \cos^2 \alpha = 0\]

(Alfvén waves)

\[C_A = \frac{B_0}{\sqrt{\mu_0 \rho_0}} \quad \text{Alfvén speed}\]

\[C_s = \sqrt{\gamma \frac{p_0}{\rho_0}} \quad \text{Sound speed}\]
Alfven Waves

\[ \omega = C_A k \cos \alpha \]

\[ \nu_A = \frac{\omega}{k} = C_A \cos \alpha \]

\[ \mathbf{v}_g = \nabla_k \omega = \nu_A \hat{\mathbf{B}} \]

- Incompressible – no change to density or pressure
- Group speed is along \( \mathbf{B} \) – does not transfer energy (information) across \( \mathbf{B} \) fields
For zero plasma-beta – no pressure

\[ \omega = C_A k \]

\[ v_A = \frac{\omega}{k} = C_A \]

\[ v_g = \nabla_k \omega = v_A \hat{k} \]

- Compresses the plasma – c.f. a sound wave
- Propagates energy in all directions
Magnetic pressure and tension

\[ \rho \frac{\partial \mathbf{v}}{\partial t} + \rho (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla p + \mathbf{j} \times \mathbf{B} \]

But...

\[ \mathbf{j} \times \mathbf{B} = -\frac{1}{2\mu_0} \nabla B^2 + \frac{1}{\mu_0} (\mathbf{B} \cdot \nabla) \mathbf{B} \]

So...

\[ \rho \frac{\partial \mathbf{v}}{\partial t} + \rho (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla \left( p + \frac{1}{2\mu_0} B^2 \right) + \frac{1}{\mu_0} (\mathbf{B} \cdot \nabla) \mathbf{B} \]
Pressure perturbations

Slow Wave

Fast Wave
Phase and group speeds

Phase speeds:

: Group speeds
Throwing a ‘pebble’ into a ‘plasma lake’...
For low plasma beta $v_A >> c_s$

Three types of MHD waves

- **Alfvén waves**
  magnetic tension ($\omega = V_A k$)

- **Fast magnetoacoustic waves**
  magnetic with plasma pressure ($\omega \approx V_A k$)

- **Slow magnetoacoustic waves**
  magnetic against plasma pressure ($\omega \approx C_s k$)
1. The perturbations are waves
2. Waves are dispersionless
3. ω and k are always real
4. Waves are highly anisotropic
5. There are incompressible - Alfvén waves - and compressible - magnetoacoustic – modes

However, natural plasma systems are usually highly structured and often unstable
Non-ideal terms in MHD

Ideal MHD is a set of conservation laws

Non-ideal terms are dissipative and entropy producing

- Resistivity
- Viscosity
- Radiation transport
- Thermal conduction
Electron-ion collisions dissipate current

\[ \mathbf{E} + \mathbf{v} \times \mathbf{B} = \eta \mathbf{j} \]

If we assume the resistivity is constant then

\[ \frac{\partial \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B}) + \frac{\eta}{\mu_0} \nabla^2 \mathbf{B} \]

Ratio of advective to diffusive terms is the magnetic Reynolds number

\[ R_m = \frac{\mu_0 L_0 v_0}{\eta} \]

Usually in space physics \( R_m \gg 1\) \((10^6\text{-}10^{12})\). This is based on global scale lengths \( L_0 \). If \( L_0 \) is over a small scale with rapidly changing magnetic field, i.e. a current sheet, then \( R_m \sim 1 \)
Alfven’s theorem

Rate of change of flux through a surface moving with fluid

\[ \frac{d}{dt} \int_S \mathbf{n} \cdot \mathbf{B} \, dS = \int_S \mathbf{n} \frac{\partial \mathbf{B}}{\partial t} \, dS - \oint_l \mathbf{v} \times \mathbf{B} \cdot d\mathbf{l} \]

\[ = - \int_S \nabla \times (\mathbf{E} + \mathbf{v} \times \mathbf{B}) \cdot \mathbf{n} \, dS \]

Magnetic flux through a surface moving with the fluid is conserved if ideal MHD Ohm’s law, i.e. no resistivity

Often stated as- the flux is frozen in to the fluid
Consider two points which move with the fluid

\[ \delta x_i = \frac{\partial x_i}{\partial X_j} \delta X_j \]

\[ \frac{D}{Dt} \delta x = \frac{\partial u_i}{\partial X_j} \delta X_j \]

\[ = \frac{\partial u_i}{\partial x_k} \frac{\partial x_k}{\partial x_j} \delta X_j \]

\[ = (\delta x \cdot \nabla) u \]
Equation for evolution of the vector between two points moving with the fluid is

\[ \frac{D}{Dt} \delta x = (\delta x \cdot \nabla) u \]

Also for ideal MHD

\[ \frac{D}{Dt} \left( \frac{B}{\rho} \right) = \frac{B}{\rho} \cdot \nabla v \]

Hence if we choose \( \delta x \) to be along the magnetic field at \( t = 0 \) then it will remain aligned with the magnetic field.

Two points moving with the fluid which are initially on the same field-line remain on the same field line in ideal MHD

Reconnection not possible in ideal MHD
Cauchy Solution

Shown that $\frac{B}{\rho}$ and $\delta x$ satisfy the same equation hence

$$\delta x_i = \frac{\partial x_i}{\partial X_j} \delta X_j$$

Implies

$$\frac{B_i}{\rho} = \frac{\partial x_i}{\partial X_j} B_j^0 \frac{\rho}{\rho^0}$$

Where superscript zero refers to initial values

$$B_i = \frac{\partial x_i}{\partial X_j} B_j^0 \frac{\rho}{\rho^0}$$

$$\frac{\rho^0}{\rho} = \Delta = \frac{\partial(x_1, x_2, x_3)}{\partial(X_1, X_2, X_3)}$$
**MHD based on Cauchy**

\[ B_i = \frac{\partial x_i}{\partial X_j} \frac{B_j^0}{\Delta} \]

\[ \frac{\rho^0}{\rho} = \Delta = \frac{\partial (x_1, x_2, x_3)}{\partial (X_1, X_2, X_3)} \]

\[ P = \text{const } \rho^\gamma \]

\[ \frac{D\mathbf{v}}{Dt} = -\frac{1}{\rho} \nabla \cdot P + \frac{1}{\mu_0 \rho} (\nabla \times \mathbf{B}) \times \mathbf{B} \]

\[ \frac{dx}{dt} = \mathbf{v} \]

Only need to know position of fluid elements and initial conditions for full MHD solution
Non-ideal MHD

\[ \frac{\partial B}{\partial t} = \nabla \times (v \times B) + \eta \nabla^2 B \]

\[ \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho v) = 0 \]

\[ \rho \frac{\partial v}{\partial t} + \rho (v \cdot \nabla) v + 2\rho \Omega \times v = -\nabla p + j \times B + \rho g + F, \]

\[ p = \frac{1}{\mu} \rho k T \]

\[ \frac{\rho^\gamma}{\gamma - 1} \frac{D}{Dt} \left( \frac{p}{\rho^{\gamma / \gamma}} \right) = \nabla \cdot (k \nabla T) - \rho^2 Q(T) + \frac{j^2}{\sigma} + H \]
Sets of ideal MHD equations can be written as

\[
\frac{\partial \mathbf{U}}{\partial t} + \frac{\partial }{\partial x} \left[ \mathbf{F}(\mathbf{U}) \right] = 0
\]

All equations sets of this types share the same properties

- they express conservation laws
- can be decomposed into waves
- non-linear solutions can form shocks
- satisfy $L1$ contraction, TVD constraints
Characteristics

\[
\frac{\partial U}{\partial t} + \frac{\partial}{\partial x} [F(U)] = 0
\]

\[
\frac{\partial U}{\partial t} + \frac{\partial F}{\partial U} \cdot \frac{\partial U}{\partial x} = 0
\]

\[
\frac{\partial U}{\partial t} + A(U) \cdot \frac{\partial U}{\partial x} = 0
\]

\(A(U)\) is called the Jacobian matrix

For linear systems can show that Jacobian matrix is a function of equilibria only, e.g. function of \(p_0\) but not \(p_1\)
Properties of the Jacobian

Left and right eigenvectors/eigenvalues are real
\[ A \cdot r_i = \lambda_i r_i \quad \text{and} \quad l_i A = \lambda_i l_i \]

Diagonalisable:
\[ A = R \Lambda R^{-1} \]

\[ \Lambda = \text{diag}(\lambda_1, \lambda_2 \ldots \lambda_m) \]

\[ R = \begin{bmatrix} r_1 & r_2 & \ldots & r_m \end{bmatrix} \]

\[ R^{-1} = L = \begin{bmatrix} l_1 \\ l_2 \\ \vdots \\ l_m \end{bmatrix} \]
This example is for linear equations with constant $A$

$$R^{-1} \left( \frac{\partial U}{\partial t} + A \frac{\partial U}{\partial x} \right) = 0$$

$$\frac{\partial}{\partial t} \left( R^{-1} U \right) + \left( R^{-1} A \right) \frac{\partial U}{\partial x} = 0$$

But $A = R \Lambda R^{-1}$ so $R^{-1} A = \Lambda R^{-1}$

$$\frac{\partial}{\partial t} \left( R^{-1} U \right) + \Lambda \frac{\partial}{\partial x} \left( R^{-1} U \right) = 0$$

$$\frac{\partial w}{\partial t} + \Lambda \frac{\partial w}{\partial x} = 0 \quad \text{with} \quad w = R^{-1} U$$

$w$ is called the characteristic field.
Riemann problems

\[ \Lambda \text{ is diagonal so all equations decouple} \]

\[ \frac{\partial w_i}{\partial t} + \lambda_i \cdot \frac{\partial w_i}{\partial x} = 0 \]

i.e. characteristics \( w_i \) propagate with speed \( \lambda_i \)

In MHD the characteristic speeds are \( v_x, v_x \pm c_f, v_x \pm v_A, v_x \pm c_s \)

i.e. the fast, Alfven and slow speeds

Solution in terms of original variables \( U \)

\[ U = R.w \]

\[ U = \sum_{i=1}^{m} w_i(x, t) r_i \]

\[ U = \sum_{i=1}^{m} w_i^{t=0}(x - \lambda_i t) r_i \]

This analysis forms the basis of Riemann decomposition used for treating shocks, e.g. Riemann codes in numerical analysis
Basic Shocks

Temperature

\[ c_s^2 = \gamma P/\rho \]

\[ T = T(x - c_s t) \]

Without dissipation any 1D traveling pulse will eventually, i.e. in finite time, form a singular gradient. These are shocks and the differentially form of MHD is not valid.

Also formed by sudden release of energy, e.g. flare, or supersonic flows.
Integrate equations from $x_l$ to $x_r$ across moving discontinuity $S(t)$
Use
\[
\frac{d}{dt} \int_{x_l}^{x_r} U(x, t) \, dx = \frac{d}{dt} \int_{x_l}^{S(t)} U \, dx + \frac{d}{dt} \int_{S(t)}^{x_r} U \, dx
\]

\[
= [U(s_-, t) - U(s_+, t)] \frac{ds}{dt} + \int_{x_l}^{S(t)} \frac{\partial U}{\partial t} \, dx + \int_{S(t)}^{x_r} \frac{\partial U}{\partial t} \, dx
\]

Let $x_l$ and $x_r$ tend to $S(t)$ and use conservative form to get

\[
(U_L - U_R) v_s = F(U_L) - F(U_R)
\]

- Rankine-Hugoniot conditions for a discontinuity moving at speed $v_s$
- All equations must satisfy these relations with the same $v_s$
The End
